20. ABSTRACT (Continue on reverse side if necessary and identify by block number) Preliminary temperature microstructure profiles resulting from the Mixed Layer Experiment at Ocean Station P (144°W, 55°N) during August-September 1977 are presented. Depth ranges plotted are from 5 meters to 70 meters. The profiles show the behavior of the mixed layer and thermocline before, during, and after two synoptic scale storms.

ACKNOWLEDGMENTS

The MSP instruments were constructed by Mr. Mark Matsler and Mr. Steven D. Wilcox. Participating in the cruise were Ms. Priscilla Newberger, Mr. Mark Matsler, and Mr. Asa Robinson. Special thanks must be given to the officers and crew of the R/V OCEANOGRAPHER, particularly Captain George Poor and Lt. William Lounsberry. The MILE experiment is funded by the Office of Naval Research.

INTRODUCTION

This report is a preliminary presentation of temperature microstructure data resulting from the Mixed Layer Experiment (MILE) at Ocean Station P (55°N , 145°W) during August-September 1977. During the MILE experiment, the Caldwell research group conducted 381 casts over a period of 21 days from the R/V OCEANOGRAPHER, using a Microstructure Profiler (MSP). Contained in this report are temperature and temperature derivative profiles over a depth range of 5 m to 70 m from 211 of those casts.

On many of these casts electrical conductivity or optical transmissivity sensors were also operating, but these were omitted in order that this report might be available to other participants in the cruise at the time of the first post-cruise meeting. At a later date we hope to publish a more complete report, adding not only salinity and transmissivity profiles, but also including a number of casts made to greater depths, often 180 m.

EXPERIMENTAL DESCRIPTION

Six MSP units, conceptually similar to the profiler described by Caldwell, Wilcox and Matsler (1975), were used. Casts began 0500 August 19, 1977 GMT and ended 1200 September 8, 1977 GMT. They took place every night but two, on which CTD surveys took place.

During the experiment, two synoptic-scale storms occurred at Station P. The first, with winds to 38 knots, began at approximately 1200 August 22, 1977 GMT, and lasted until 1400 August 24, 1977. The second was milder, with winds to 33 knots, and lasted from 1200 August 31, 1977 GMT until 0000 September 2, 1977 GMT (Figure 1). Casts were made before, during, and after each storm, and reflect the effect of mixing brought about by the storms and the relaxation to a more quiescent state following each storm.

The schedule of observations began after local sundown and ended before local sunrise, thus aliasing events with a diurnal time scale. Large excursions of temperature structures within the thermocline region were noted which may often be attributable to internal wave activity. An attempt was made to hold station relative to the MILE I mooring during a sequence of casts; however, both ship drift and advection insure that the same water column is not sampled twice, so that the profiles also show the effects of horizontal inhomogeneities. Thus, it is often difficult to attribute changes in features between casts to either temporal or spatial effects alone.

Temperature and pressure calibrations for each unit were performed before the cruise. Post-cruise calibrations revealed that the electronic circuit characteristics were quite stable during the cruise. The temp-

erature versus resistance characteristics of the thermistors did not fare as well, showing a marked drift during the cruise. Since our interest in this report is in small-scale features rather than in absolute accuracy, corrections have not been made for this calibration shift. The profiles shown in this report make use of pre-cruise calibrations only, and no attempt was made to normalize the profile to CTD measured temperatures. Measurements with different MSP units should therefore be treated with some caution.

PROFILE PRESENTATION

Since the typical drop speed of the MSP is about 12 cm/sec and the sampling rate was 90 per second, the typical resolution was 0.13 cm. The record was decimated without averaging to obtain a mean plot density of 200 points per inch. This procedure results in aliasing errors, but was thought to give a better representation of the true high-frequency nature of the temperature derivative signal than could be obtained by plotting averages.

The vertical scale of the temperature profile is depth (meters) and the horizontal scale is degrees (centigrade). The scale of the temperature depth derivative is given in the upper left of each plot. Also given above each plot is the MSP unit (A,B,C,D, or E) with which the data was taken. Next to the unit name is the drop name, which is unique to each cast. Below the plot is given the date and time (GMT).

Near the top of each plot is a small square showing the position at which the cast was taken relative to the MILE I mooring. The sides of the square represent 10 km. True north is upward. The ship position is marked as "x" and the MILE I mooring is marked "+". Below the plot is given the range (km) and bearing (degrees) of the buoy as measured from the vessel.
