The cost of multiple sclerosis drugs in the US and the pharmaceutical industry: Too big to fail?

The cost of multiple sclerosis drugs in the US and the pharmaceutical industry

Too big to fail?

ABSTRACT

Objective: To examine the pricing trajectories in the United States of disease-modifying therapies (DMT) for multiple sclerosis (MS) over the last 20 years and assess the influences on rising prices.

Methods: We estimated the trend in annual drug costs for 9 DMTs using published drug pricing data from 1993 to 2013. We compared changes in DMT costs to general and prescription drug inflation during the same period. We also compared the cost trajectories for first-generation MS DMTs interferon (IFN)-β-1b, IFN-β-1a IM, and glatiramer acetate with contemporaneously approved biologic tumor necrosis factor (TNF) inhibitors.

Results: First-generation DMTs, originally costing $8,000 to $11,000, now cost about $60,000 per year. Costs for these agents have increased annually at rates 5 to 7 times higher than prescription drug inflation. Newer DMTs commonly entered the market with a cost 25%–60% higher than existing DMTs. Significant increases in the cost trajectory of the first-generation DMTs occurred following the Food and Drug Administration approvals of IFN-β-1a SC (2002) and natalizumab (reintroduced 2006) and remained high following introduction of fingolimod (2010). Similar changes did not occur with TNF inhibitor biologics during these time intervals. DMT costs in the United States currently are 2 to 3 times higher than in other comparable countries.

Conclusions: MS DMT costs have accelerated at rates well beyond inflation and substantially above rates observed for drugs in a similar biologic class. There is an urgent need for clinicians, payers, and manufacturers in the United States to confront the soaring costs of DMTs. Neurology® 2015;84:2185-2192

GLOSSARY

AWP = average wholesale price; DMT = disease-modifying therapy; FDA = Food and Drug Administration; IFN = interferon; MS = multiple sclerosis; QALY = quality-adjusted life-year; TNF = tumor necrosis factor; VA = Veterans Affairs; WAC = wholesale acquisition cost.

The landscape of multiple sclerosis (MS) treatment has changed dramatically over the last decade. As of November 2014, 12 disease-modifying therapies (DMTs) for MS have been approved by the US Food and Drug Administration (FDA). Despite the availability of more treatment options, costs for all MS DMTs have increased sharply. Between 2008 and 2012, US DMTs sales doubled from $4 billion to nearly $9 billion annually.1 In 2004, the average annual DMT cost per person was $16,050, accounting for half of all direct medical costs for patients with MS.2 Currently, the average annual cost for interferon (IFN)–β-1b (Betaseron; Bayer HealthCare Pharmaceuticals, Whippany, NJ) is over $60,000.3 Although high drug costs are a hallmark of specialty pharmaceutical classes, such as DMTs, the unexplained escalation in costs for older, first-generation MS therapies such as IFN-β-1b, IFN-β-1a IM (Avonex; Biogen Idec, Cambridge, MA), and glatiramer acetate (Copaxone; Teva Pharmaceuticals, North Wales, PA) has caused concern in the neurology community.4,5

The objectives of this study were to (1) investigate our impression that costs for all MS DMTs have increased dramatically since 2002, (2) explore the relationship between the release of newer
DMTs and the trend in costs for older DMTs, and (3) compare DMT costs in the United States to those in other countries. This study suggests the need for the neurology community to advocate for changes in the pricing of MS treatments.

**METHODS** Although the FDA had approved 12 DMTs for MS as of November 2014, we did not include 3 in our analysis. Cost data were not available at the time of our analysis for the 2 most recently approved DMTs: peginterferon-β-1a (Preglizy; Biogen Idec) and alemtuzumab (Lemtrada; Genzyme, Cambridge, MA). Mitoxantrone (generic, multiple manufacturers), approved in 2000 for MS, was excluded because it is much less commonly used to treat MS due to safety concerns. For the remaining 9 FDA-approved drugs, we computed the average annual acquisition costs for each month from July 1993 (approval date for IFN-β-1b) through December 2013. We estimated acquisition costs using average wholesale price (AWP) published by First DataBank. Although most third-party payers have moved away from AWP-based reimbursement formulas, it was the prevailing methodology for most of the study period and provides a consistent measure of price for comparisons of change over the past 20 years. AWP reporting was phased out in 2011 and acquisition costs were then estimated using wholesale acquisition cost (WAC) with the conversion AWP = 1.2 × WAC. We applied a 12% discount to AWP, the median discount that state Medicaid programs reimburse pharmacies, to estimate the amount paid to pharmacies by third-party payers.

We then computed the effective percentage increase in annual costs and compared this to changes in the consumer price index for prescription drugs and all consumer goods and services (general inflation) over the same period using data from the US Bureau of Labor Statistics.

Next, we compared the median annual cost trends for first-generation MS DMTs IFN-β-1b, IFN-β-1a IM, and glatiramer acetate to the contemporaneously approved biologic tumor necrosis factor (TNF) inhibitors etanercept (Enbrel; Amgen, Thousand Oaks, CA) and adalimumab (Humira; AbVie, North Chicago, IL) using segmented regression analyses. We computed annual costs for TNF inhibitors using the same approach described for the MS drugs based on FDA-approved doses for rheumatoid arthritis. Annual costs were estimated quarterly beginning the fourth quarter of 1998 (the quarter etanercept was approved) until the fourth quarter of 2013 (61 total quarters). Four major periods of change were examined: (1) a baseline period preceding the approval of IFN-β-1a SC (Rebif; EMD Serono, Rockland, MA) (fourth quarter 1998 to first quarter 2002); (2) a period from the approval of IFN-β-1a SC to the re-introduction of natalizumab (Tysabri; Biogen Idec) (second quarter 2002 to second quarter 2006); (3) a period from the re-introduction of natalizumab to the approval of fingolimod (Gilenya; Novartis Pharmaceuticals, East Hanover, NJ) (third quarter 2006 to third quarter 2010); and (4) a period following the approval of fingolimod (fourth quarter 2010 to fourth quarter 2013). We selected the re-introduction date for natalizumab (June 2006–second quarter 2006) because it was only available for 2 months before marketing was suspended in 2005 to evaluate the risks of progressive multifocal leukoencephalopathy.

The general form of the segmented regression model (without interaction parameterization) was \[ \log(Y_t) = \beta_0 + \beta_1 \times \text{Time} + \beta_2 \times \text{Rebif} + \beta_3 \times \text{Time Rebif} + \beta_4 \times \text{Tysabri} + \beta_5 \times \text{Time Tysabri} + \beta_6 \times \text{Gilenya} + \beta_7 \times \text{Time Gilenya} + \beta_8 \times \text{Fingolimod} + \varepsilon, \]

We log-transformed the dependent variable annual cost because initial plots of quarterly data were nonlinear. Because of this, the estimated \( \beta \)-coefficients are interpreted as a percent change. For each period, we report the quarterly percentage change (trend) in median costs for DMTs and TNF inhibitors individually and relative to each other. The results of the segmented regression analyses were performed using PROC AUTOREG in SAS version 9.2 (SAS Institute, Cary, NC).

Finally, we compared the most recent annual cost of therapy for each DMT to US dollar-adjusted costs from the United Kingdom, Canada, and Australia, a convenience sample of developed countries with accessible cost data. The following conversion rates (as of April 2, 2014) for cost data were applied: Canada (0.91), United Kingdom (1.66), Australia (0.92). In the United Kingdom, the National Health Service publishes net prices in the British National Formulary. Canadian drug costs were estimated using drug benefit prices published through Ontario’s Exceptional Access Program, although costs can vary by province. Drug costs in Australia are listed in an online compendium of the Australian Pharmaceutical Benefit Scheme and represent agreed-upon prices paid by the Commonwealth of Australia. We also examined costs paid by the US Department of Veterans Affairs (VA) because of their ability to negotiate discounts directly with manufacturers. VA costs were estimated using Big Four pricing (or Federal Supply Schedule price if no Big Four price was listed) available through the online VA National Formulary. For comparative purposes, we further adjusted US costs to account for federally mandated rebates paid to the Medicare program. Appendix e-1 on the Neurology Web site at Neurology.org contains details of our cost and statistical modeling methods.

**RESULTS** First-generation DMTs IFN-β-1b, IFN-β-1a IM, and glatiramer acetate were introduced with annual acquisition costs between $8,292 and $11,532 (table 1). Over subsequent decades, costs for these DMTs rose on average 21%–36% annually. Costs of the most recently approved oral agents fingolimod, teriflunomide (Aubagio; Genzyme), and dimethyl fumarate (Tecfidera; Biogen Idec) have increased 8%–17% annually since their approval. In contrast, general and prescription drug inflation only increased 3%–5% per year during the same period. The acquisition cost of IFN-β-1b, the oldest DMT on the market, is now $61,529 a year, roughly 6 times its original cost. The cost trajectories for IFN-β-1a IM and glatiramer acetate were similar. Without accounting for any potential manufacturer rebates, there are currently no MS DMTs with an annual cost less than $50,000 per year.

The dramatic increase in costs of the first-generation DMTs was not uniform over the last 20 years. Costs for first-generation DMTs increased modestly between 1993 and 2001 (figure 1). IFN-β-1a SC, a recombinant IFN-β similar to IFN-β-1b and IFN-β-1a IM, entered the market in March 2002 with an annual cost of $15,262, 30%–60% higher than the 3 other available DMTs. The annual cost of natalizumab, the first monoclonal antibody for MS, at initial release (November 2004) was $25,850, over 50% higher than IFN-β-1b, IFN-β-1a IM, and glatiramer.

Abbreviation: CPI = consumer price index.
*Interferon-β-1b is marketed as both Betaseron (Bayer) and Extavia (Novartis).
Natalizumab was withdrawn from the market in February 2005 to evaluate progressive multifocal leukoencephalopathy risk and was reintroduced in June 2006.

We sought to determine whether the introduction of new MS DMTs influenced the rate of increase in cost for the first-generation DMTs and, as a comparison, used changes in the cost of the TNF inhibitors (figure 2). During the baseline period of 1998–2001, costs for DMTs and TNF inhibitors increased significantly by 1.4% (p < 0.0001) and 2.2% (p < 0.0001) per quarter, respectively. During this period, the quarterly rate of increase was significantly higher for the TNF inhibitors (p = 0.0001). Following the introduction of IFN-β-1a SC, the trend in costs for first-generation DMTs increased significantly to 3.3% per quarter (p < 0.0001 for change in trend). In contrast, the rate of growth for the TNF inhibitors decreased significantly to 1.3% per quarter (p = 0.0001 for change in trend) and was statistically lower than the DMT trend change (p < 0.0001 for change in trend interaction). The re-introduction of natalizumab in 2006 was followed by another significant increase in the trend of first-generation DMT costs to 4.6% per quarter (p < 0.0001 for change in trend). During the same period, there was no significant change in the trend for the TNF inhibitors and the difference between the 2 classes was statistically significant (p < 0.0001 for change in trend interaction). Fingolimod was approved in the third quarter of 2010. Although growth in first-generation DMT costs moderated to 3.7% per quarter, it remained significantly above the quarterly growth rate for the TNF inhibitors trend, which increased to 3.1% per quarter (p = 0.0183 for period trend interaction).

After accounting for federally mandated Medicaid rebates, annual costs for DMTs in the United States ranged from $41,078 for IFN-β-1b (Extavia; Novartis Pharmaceuticals) to $53,032 for IFN-β-1a SC. Annual DMT costs were often more than 70% lower in the 3 comparator countries (table 2). Costs for the VA were, on average, 36% less than those paid by Medicaid, but ranged from a nearly 80% discount for IFN-β-1b to a 19% discount for fingolimod.

**DISCUSSION** This study documents the alarming rise in costs for MS DMTs in the United States since 2002. While we would expect that legitimate advances, such as the development of oral DMTs, might garner higher prices, the escalation in costs for first-generation agents that have been available for up to 2 decades is puzzling. Our analyses show that cost increases for IFN-β-1b, IFN-β-1a IM, and glatiramer acetate were many times higher than prescription drug inflation. First-generation MS DMT costs substantially outpaced those for a contemporaneous class of TNF inhibitor biologic agents, accelerating upwards following introduction of each new MS DMT. These results suggest that the dramatic increases in the costs of the first-generation DMTs may have been a response to the introduction of competing treatments with higher prices. The reasons for this are unclear. Classic economic theory asserts that competition should reduce or stabilize costs for the consumer as more products enter the market. However, our data suggest prices of existing DMTs paradoxically rise, quickly matching prices set by the newest competitor. Costs of MS DMTs are substantially

© 2015 American Academy of Neurology. Unauthorized reproduction of this article is prohibited.
higher in the US market than in the other countries we highlight, suggesting the dramatic increases in costs in the United States are not demanded by increases in manufacturing costs or other changes out of the control of the pharmaceutical industry.

Why the costs of MS DMTs in the United States have risen so dramatically is uncertain. However, the simplest explanation is that pharmaceutical companies raise prices of new and old MS DMTs in the United States to increase profits and our health care system puts no limits on these increases. Unlike most industrialized countries, the United States lacks a national health care system to negotiate prices directly with the pharmaceutical industry. The US Medicare program, the largest single-payer health care system in the United States, is legally prohibited from negotiating drug prices directly with the pharmaceutical industry. Pharmaceutical pricing and purchasing is
complex and one of the least transparent transactions in health care. Government-issued patent monopolies, third-party payers, lack of reimbursement transparency, and imperfect clinical information all contribute to a seemingly dysfunctional marketplace where expanded choice has led to higher, rather than lower, prices. Some argue that recent trends in industry pricing suggest collusive behavior between manufacturers, although this is challenging to prove with price data alone.20 Similar to the MS DMTs, noncompetitive markets have produced rapid and coordinated rises in unit prices for drugs used to treat hemophilia.21,22 Our data add to a body of literature suggesting that branded pharmaceuticals in the same therapeutic class likely compete against each other on aspects other than price.23–25

Figure 2  Segmented time series of median annual cost in the United States for first-generation multiple sclerosis disease-modifying therapies relative to tumor necrosis factor inhibitors

Disease-modifying therapies (DMTs) are interferon (IFN)-β-1b, IFN-β-1a IM, and glatiramer acetate and tumor necrosis factor (TNF) inhibitors are etanercept and adalimumab. Trends are % change in median annual cost per quarter. With the exception of the first (baseline) period, p values reflect changes in trend from one period to the next. Complete model results are reported in appendix e-1.
It is also unclear why the MS DMT pricing trajectory is so different from that of the TNF inhibitors. One possible explanation is that TNF inhibitors face significant price competition from generic drugs in most therapeutic applications (e.g., generic disease-modifying anti-rheumatic drugs such as methotrexate and hydroxychloroquine). Although the evidence is mixed, there are some data suggesting that generic drug entry may slow the growth of competing branded drug prices.25

Generic drugs are one of the most effective checks on rising drug costs in the United States.26 However, most MS DMTs are complex biologic agents and not exposed to price competition from generics. The Biologics Price Competition and Innovation Act of 2009 was intended to develop a generic pathway for biologics through the approval of biosimilars. Because the evidentiary requirement for a biosimilar is substantially higher than for small-molecule agents, biosimilar applications have been slow to emerge.27 Historically, the pharmaceutical industry has fought efforts to undermine their branded monopolies through the traditional Hatch-Waxman generic drug pathway.28 Teva Pharmaceuticals, which manufactures a variety of generic small-molecule drugs, has aggressively pursued several strategies to mitigate potential financial losses following the expiration of its patents on glatiramer acetate in May 2014. Patent infringement lawsuits brought against Momenta Pharmaceuticals by Teva threaten to delay the release of a generic version of glatiramer acetate.29 In addition, through a process commonly known as evergreening, Teva has been actively converting current glatiramer acetate patients to a recently approved higher dose 3 times a week formulation in an effort to protect their franchise.4,30,31 Barriers and regulatory loopholes make economic relief in the form of generic competition unlikely in the near future.

The primary limitation to our analysis concerns the estimation of drug costs. As previously noted, third-party reimbursement of pharmaceuticals is not transparent, and actual costs are often driven by proprietary contractual discounts and rebates. Therefore, the list price, commonly estimated by AWP or WAC, frequently does not reflect the ultimate cost to the payer net these discounts and rebates. With a few exceptions (most notably the VA), the US Medicaid program is legally entitled to receive best prices on medications in the United States. Although we have attempted to estimate net costs to a typical state Medicaid program by adjusting for average rebates, the actual rebate amounts are not publicly available and therefore the actual costs are not known.

The high cost of MS DMTs in the United States is producing a cascade of negative effects upon patients with MS and their medical care. In what appears to be a direct response to the high cost of these drugs, insurance carriers have developed tiered formularies requiring step-wise DMT trials, with the tiers apparently determined by preferential pricing contracts rather than any objective analysis of risks and benefits of the various therapies.32,33 In our experience, initial

denials of coverage for DMTs for both new and established patients are occurring much more frequently now than in years past, requiring multiple approval steps for patients and their neurologists.

Our results shed light on systemic problems with pharmaceutical pricing in the United States, with relevance beyond drugs for MS. The escalating costs of specialty pharmaceuticals for conditions such as MS, cancer, and hepatitis C have been a growing concern among health care payers, policy-makers, clinicians, and patients. 

Recently, some in the medical community have begun to question the ethics of our current free-market drug pricing system and to acknowledge that exorbitant pricing for drugs is a major burden on our already stressed health care system. 

While it is important for neurologists and MS advocacy groups to work on maintaining access for patients to all the MS DMTs, it may be even more critical to address DMT costs as a root cause of the access issues.

Recent cost-utility studies suggest the incremental cost per quality-adjusted life-year (QALY) for MS DMTs relative to supportive care are high, with one analysis reporting estimates in excess of $900,000 per QALY, several fold higher than traditionally accepted thresholds of what is believed to be cost-effective. One cost-effectiveness study found that the cost to prevent an MS relapse exceeded $80,000 for several IFNs and glatiramer acetate. Dramatic increases in the cost of MS DMTs without significant improvements in efficacy will only further reduce the cost-effectiveness of these drugs. Sensitivity analyses suggest that incremental cost-effectiveness ratios for MS DMTs would approach accepted thresholds if US drug costs were reduced to levels similar to the United Kingdom. 

The prices for MS drugs in the United Kingdom, Canada, and Australia, and the more controlled drug costs in large integrated health care systems, such as the VA, suggest that solutions are possible.

A flourishing pharmaceutical industry provides invaluable benefit to society by developing new drugs to combat disease and alleviate suffering. The success of the pharmaceutical industry in bringing new therapies to market for the treatment of MS has improved the care of people with MS. However, the unbridled rise in the cost of MS drugs has resulted in large profit margins and the creation of an industry “too big to fail.” It is time for neurologists to begin a national conversation about unsustainable and suffocating drug costs for people with MS—otherwise we are failing our patients and society.

17 years between launch and 2013—imply a price of approximately $1,620,721 rather than the actual price of $62,394. The correct answer for Avonex is a more modest 12% annual change (note that the error is greater the more years since a product launch).

CPI calculation errors are much smaller so that the differences between drug and CPI changes are also not maintained when corrected. Thus the difference from CPI is also more modest. While these corrected price increases (and differences from CPI increases) may still suggest further exploration, a 12% annual price increase is not as striking as the claimed 34.6%.

Author Response: Daniel M. Hartung, Dennis N. Bourdette, Sharia Ahmed, Ruth H. Whitham, Portland, OR: We thank Dr. Rittenhouse for his interest in our article. Dr. Rittenhouse is correct that in table 1 we report the annualized change as the overall percentage increase divided by the number of years since market approval for each DMT and the 2 CPIs corresponding to the same time periods. This allowed us to show changes in each DMT from introduction onto the market until December 2013 and compare these with the changes in CPI for the corresponding time period. We agree that the labels used for the 3 columns could lead some readers to misconstrue the data as being the annual growth rate.

We could have presented the data as a cumulative percentage change in price from marketing approval to the present rather than an annualized percentage increase. The ratio of the cumulative increase in DMT prices to CPI increases would remain unchanged from table 1. For example, there has been a 615% cumulative increase in the price of Avonex relative to an 84% cumulative increase in CPI for prescription drugs since introduction of the DMT until December 2013, a greater than 7-fold difference. For all the MS DMTs, price changes exceed prescription drug inflation during the same period by at least 3-fold.

We appreciate the opportunity to clarify the labeling and method used to generate the data presented in table 1. However, this clarification does not alter our analyses or conclusions about the rapid rise in MS DMT costs since 2002.

The cost of multiple sclerosis drugs in the US and the pharmaceutical industry: Too big to fail?

In the article “The cost of multiple sclerosis drugs in the US and the pharmaceutical industry: Too big to fail?” by D.M. Hartung et al. (Neurology® 2015;84:2185–2192), there is an error in table 1. Columns 5–7 should have been labeled “cumulative percent change per year” rather than “annualized changes.” The authors regret the error.

Role for the microtubule-associated protein tau variant p.A152T in risk of α-synucleinopathies

In the article “Role for the microtubule-associated protein tau variant p.A152T in risk of α-synucleinopathies” by C. Labbé et al. (Neurology® 2015;85:1680–1686), originally published ahead of print on September 2, 2015, there is an omission in the author list. The missing author, Andreas Puschmann, MD, PhD, should appear between Michael G. Heckman and Allan McCarthy in the author list. A corrected version was posted on September 25, 2015. The authors regret the omission.
