

The Economic Impact of Spatial Closures

Evidence from the Steller Sea Lion Protective Measures in the North Pacific

Matt Reimer

Alan Haynie

Alaska Fisheries Science Center, NOAA

Motivation

- Spatial closures are a prominent tool for ecosystem-based management
 - Potential benefits have been discussed thoroughly in the literature
- Ex-post estimates of the short-run costs incurred by fishing industry are relatively scarce.

Why Are Closures Costly?

- Forgone harvests and revenues:
 - Can fishers catch target species in other areas?
 - Do other areas yield lower-valued products?
 - Can fishers target other species?
 - Are other target species less valuable?
- Increased operating costs:
 - Do other areas have lower CPUE?
 - Do fishers incur higher costs fishing other areas/species (e.g. fuel and/or processing)?
- Impacts of closures will be context-specific

Challenges for Estimating the Costs of Closures

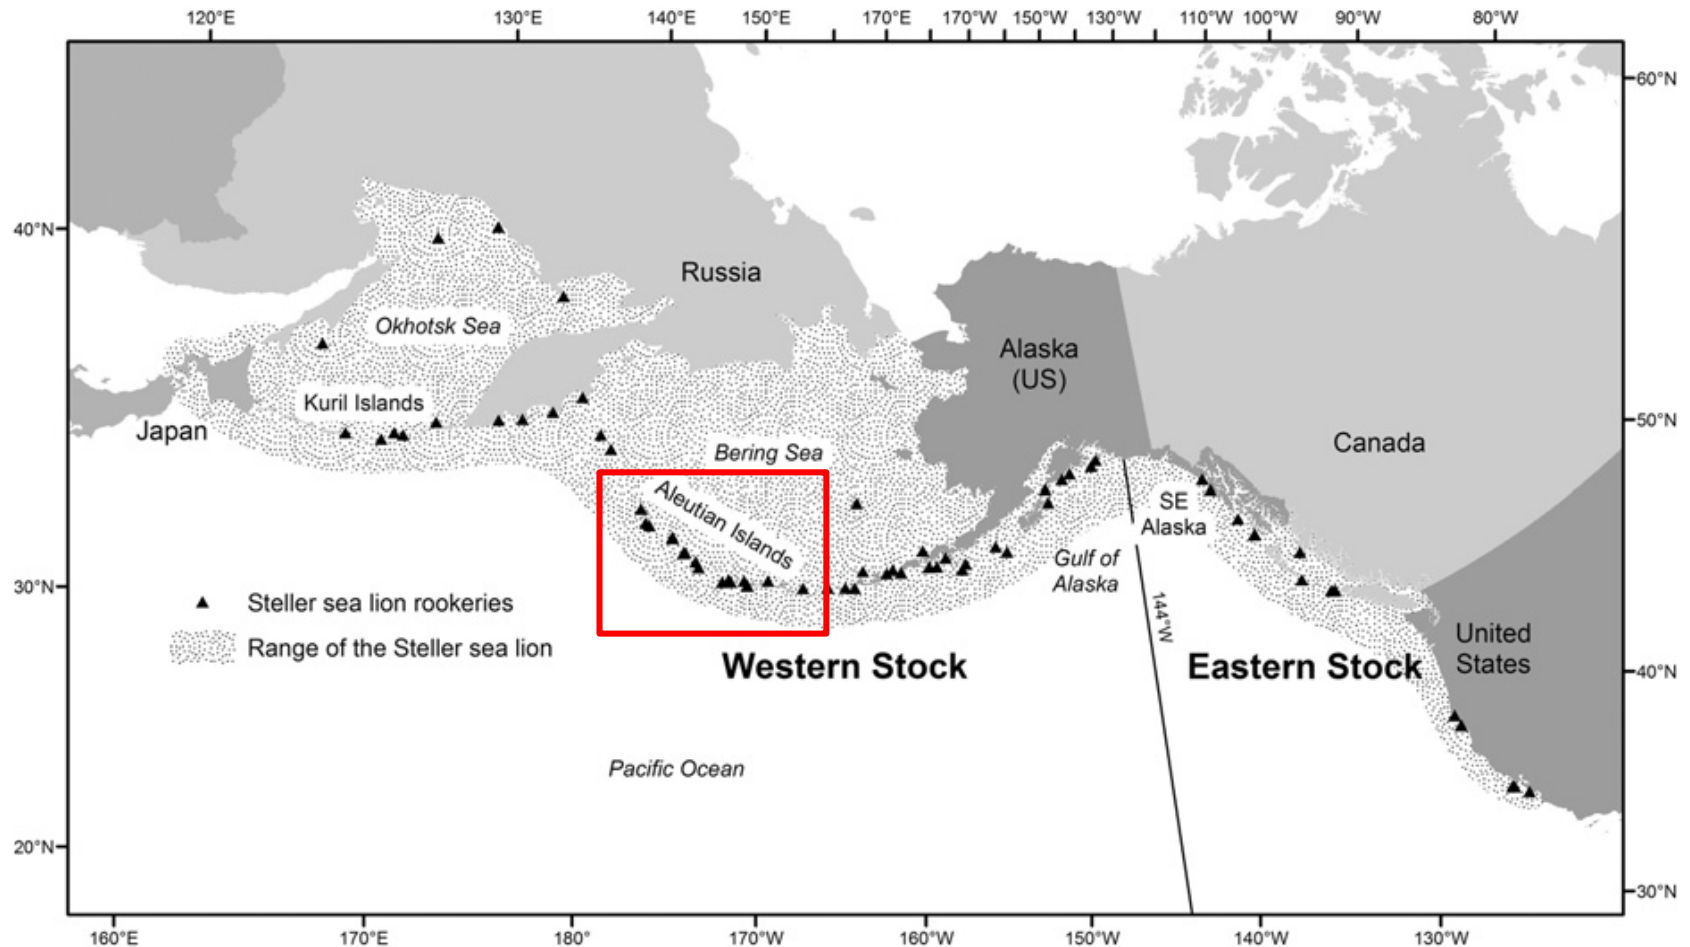

- No plausible estimate of the counterfactual:
 - *What would revenues/costs have been in the absence of the closures?*
 - Closures not designed with *ex-post* evaluation in mind
- Lack of economic data:
 - Revenue and catch data often exist
 - Cost data are relatively rare

Estimating the Cost of Closures

- We estimate the short-run costs of a large spatial closure to protect Stellar Sea Lions.
 - Multi-species fishery with harvester cooperatives
- We have a plausible estimate of the counterfactual:
 - Not all vessels were directly affected by closure
 - Comparative case study: Diff-in-diff, synthetic control
- We have annual revenue and cost data:
 - Vessels required to complete Economic Data Reports (EDR) on an annual basis.

Stellar Sea Lion Range

rine Policy 38 (2013) 523–530

Stellar Sea Lion Protection Measures

- Listed as “threatened” under ESA in 1990 and “endangered” in 1992
- Rely for food on commercial species: walleye pollock, Atka mackerel, and Pacific cod
- Protective measures:
 - Closures near SSL critical habitat
 - Seasonal and spatial TAC

Stellar Sea Lion Protection Measures

- ESA consultation finds previous measures “ineffective” (2010)
- Additional measures implemented in 2010:
 - More (and larger) spatial closures to Atka mackerel and Pacific cod fisheries

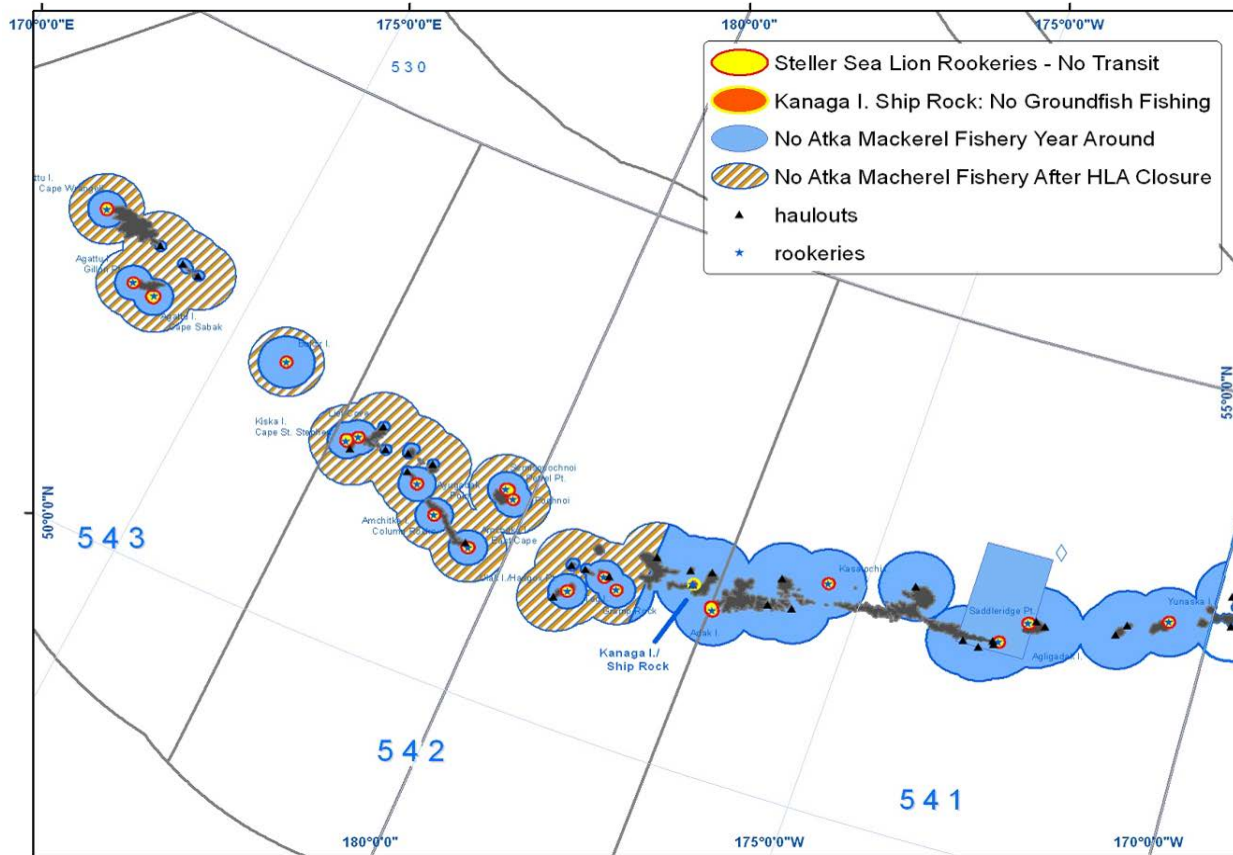

Aleutian Islands Commercial Fisheries

- Atka mackerel
 - One fleet of catcher processors (7 vessels)
 - 2008-2010: Average 61,000mt (\$61.6 million wholesale), 25% in area 543
- Pacific cod
 - Multiple fleets, variety of vessels/gear
 - 2008-2010: Average 24,000mt (\$24.1 million wholesale)
- Regulatory Impact Review
 - \$24-47 million wholesale “at risk” for Atka mackerel CPs

Aleutian Islands Commercial Fisheries

- Focus on just the Atka mackerel CPs. Why?
 - We have a plausible control group for estimating the counterfactual
 - We have annual revenue and cost data:
 - Revenues from selling product and leasing quota
 - Operating expenditures (e.g. fuel, labor, food, fish taxes, etc.)
 - 3 years before, 4 years after, 17 vessels, a total of 119 observations

SSL Protective Measures

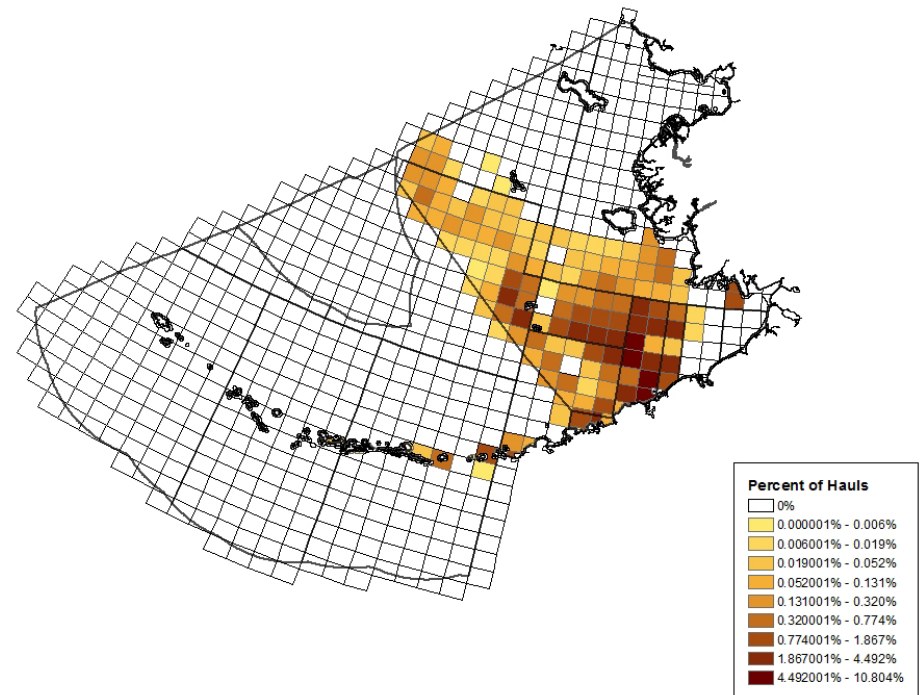

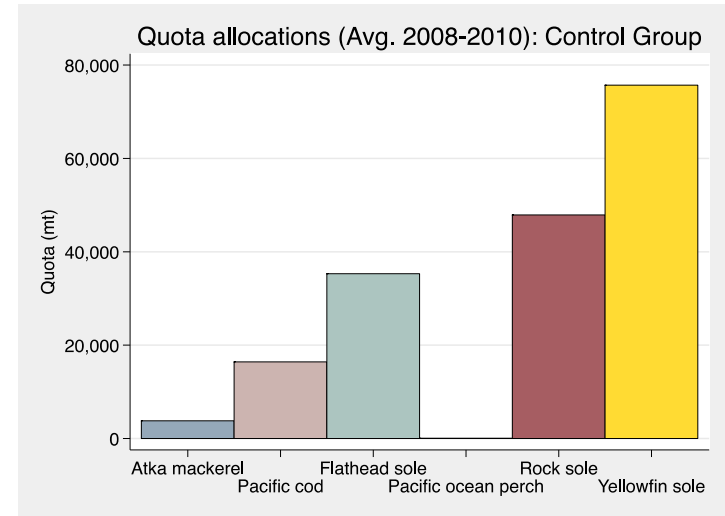

Estimating the Impact: Identification

- Counterfactual: *annual net revenues (revenue – variable costs) that would have been earned in the absence of the closure.*
- Strategy:
 - Atka mackerel vessels part of a larger fleet of similar vessels not directly affected by closure
 - Use unaffected vessels as a control group for the Atka mackerel vessels (i.e. the treated group)

Treated Group (N=7)

Control Group (N=11)

Difference-in-Differences

$$Y_{it} = \alpha + \phi_i + \theta_t + \delta treat_i \times post_t + X'_{it}\beta + \varepsilon_{it}$$

- X_{it} = [weighted price, total quota]
- Key assumptions:
 - “Parallel trends”
 - Unobserved time-varying factors affect all vessels the same
 - Exogeneity
 - Estimate the average treatment on the treated (ATT)
 - No spillover or contamination of control group

Parallel Trends

Difference-in-Differences: with quota

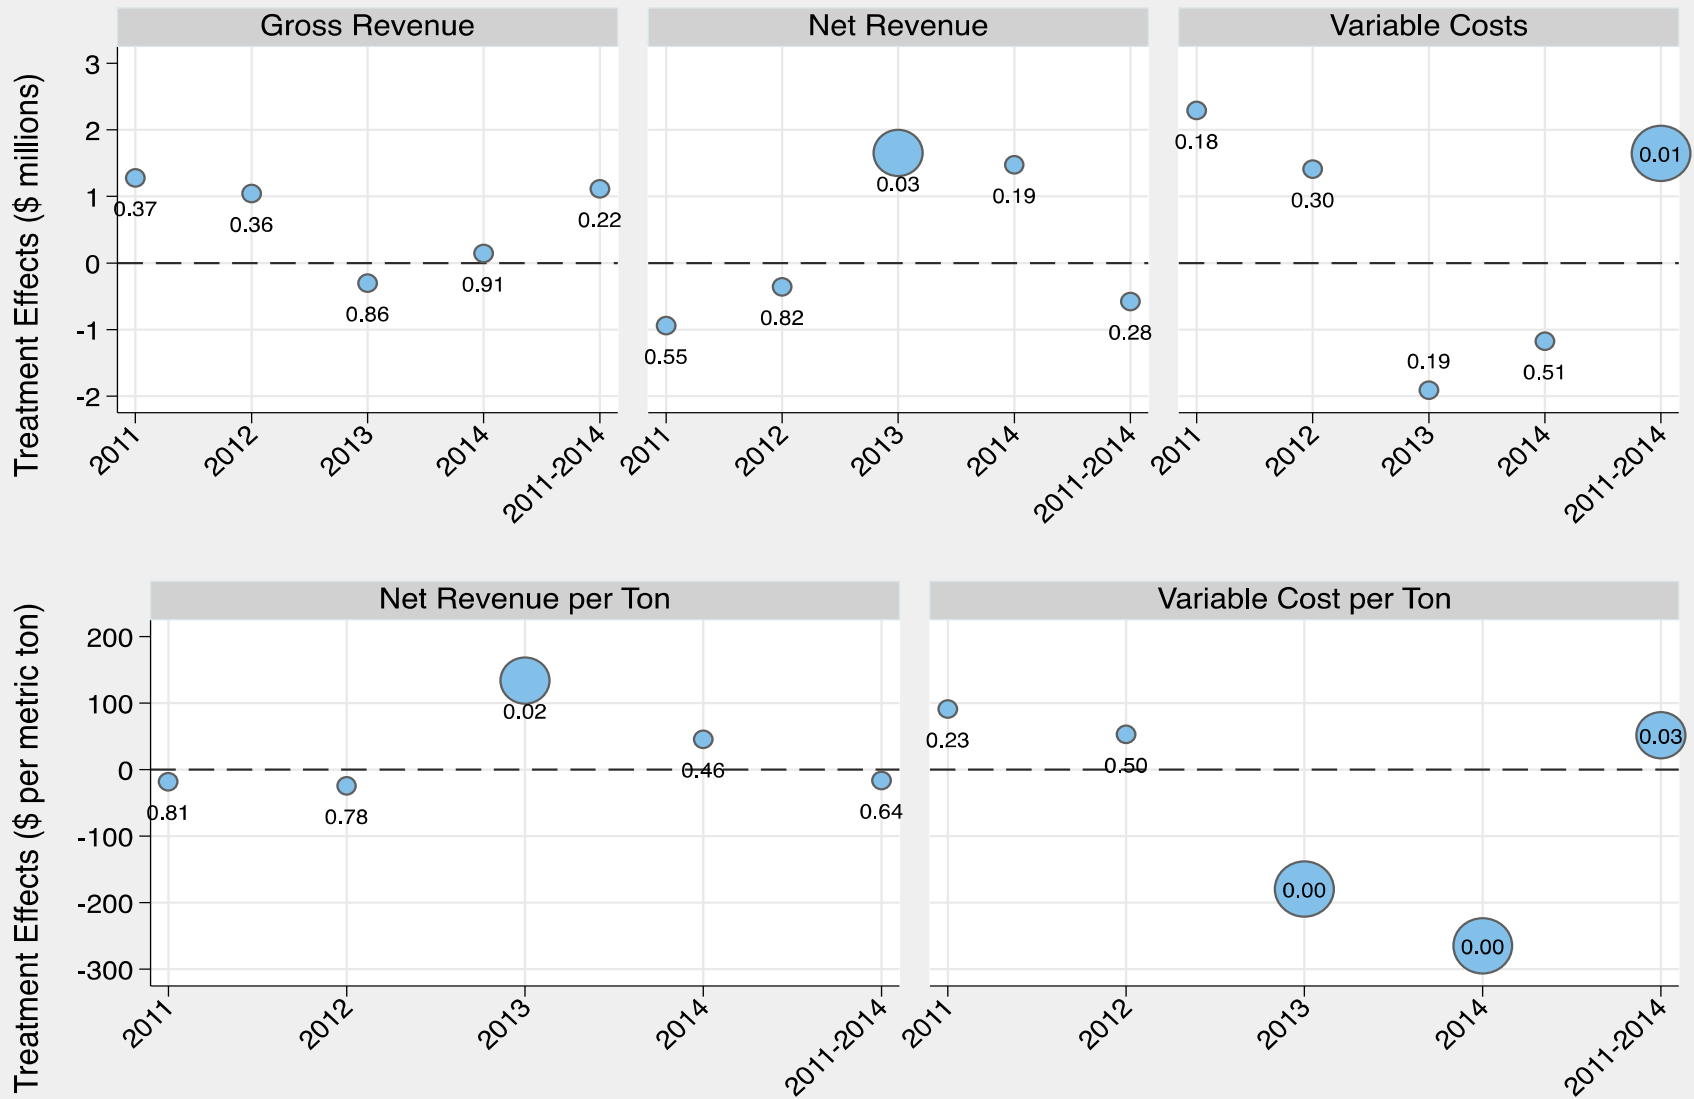

● 2011 ■ 2012 × 2013 ○ 2014 □ 2011-2014

Difference-in-Differences: without quota

● 2011 ■ 2012 × 2013 ● 2014 □ 2011-2014

Difference-in-Differences: Permutation

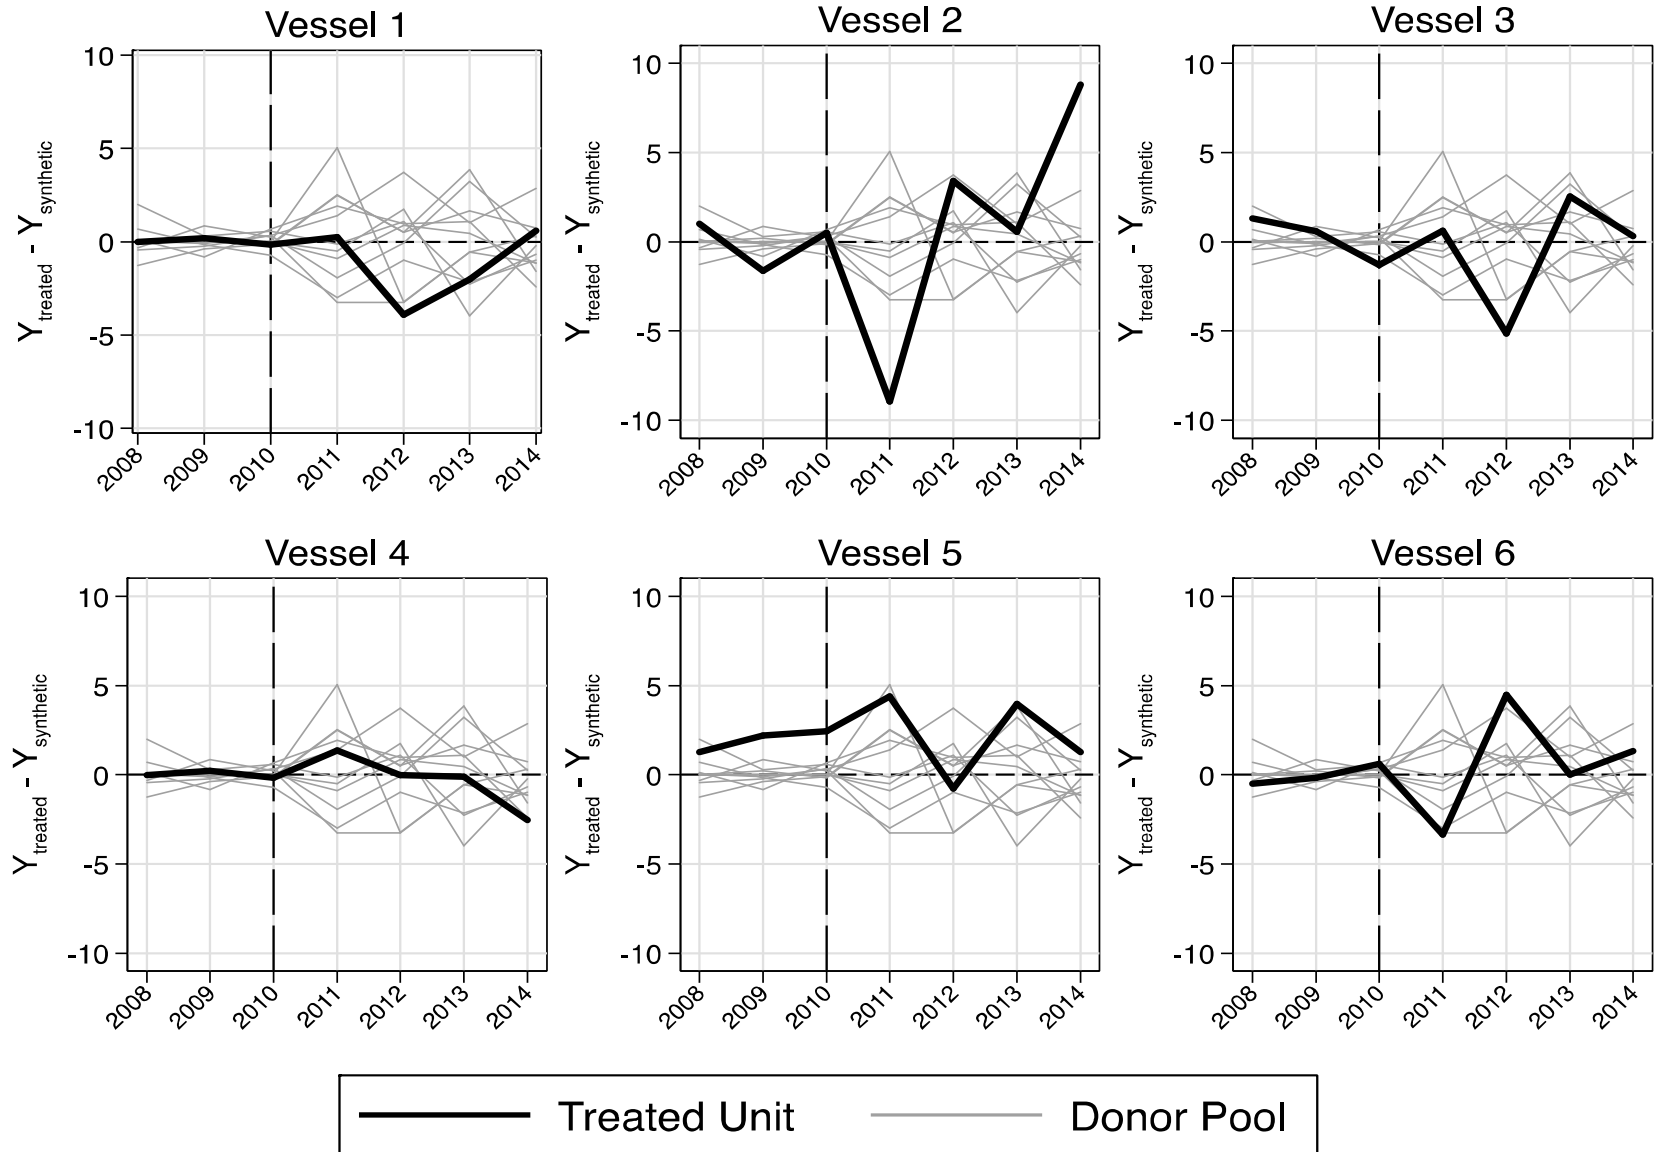

Synthetic Control Method

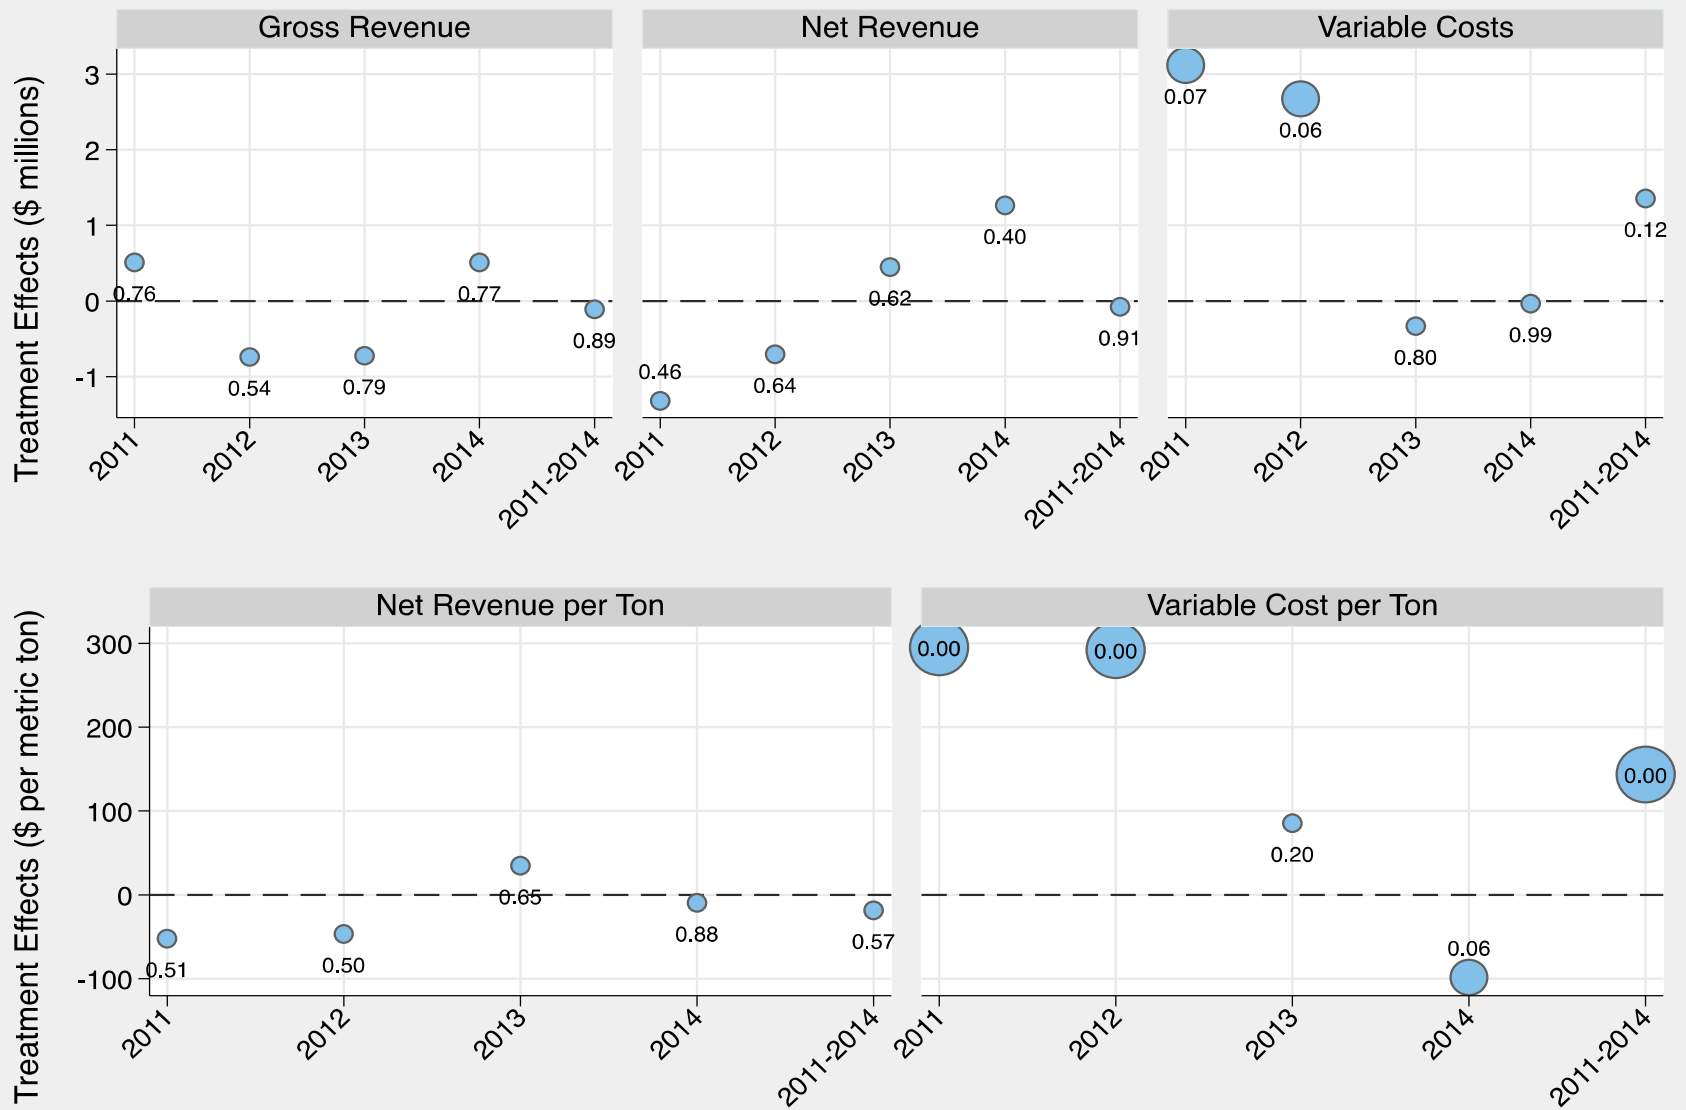

$$\hat{\delta}_{it} = Y_{it} - \sum_{j \neq i} w_j^* Y_{jt}, \quad t \in \{T_0 + 1, \dots, T\}$$

- SCM generalizes diff-in-diff, with advantages:
 - Data-driven process to construct comparison group (Abadie et al., 2010)
 - Allows the effects of unobserved vessel-specific factors to vary with time
 - Allows for heterogeneity in treatment effects across vessels

Synthetic Control Results: Net Revenues

Synthetic Control Results: DnD effects

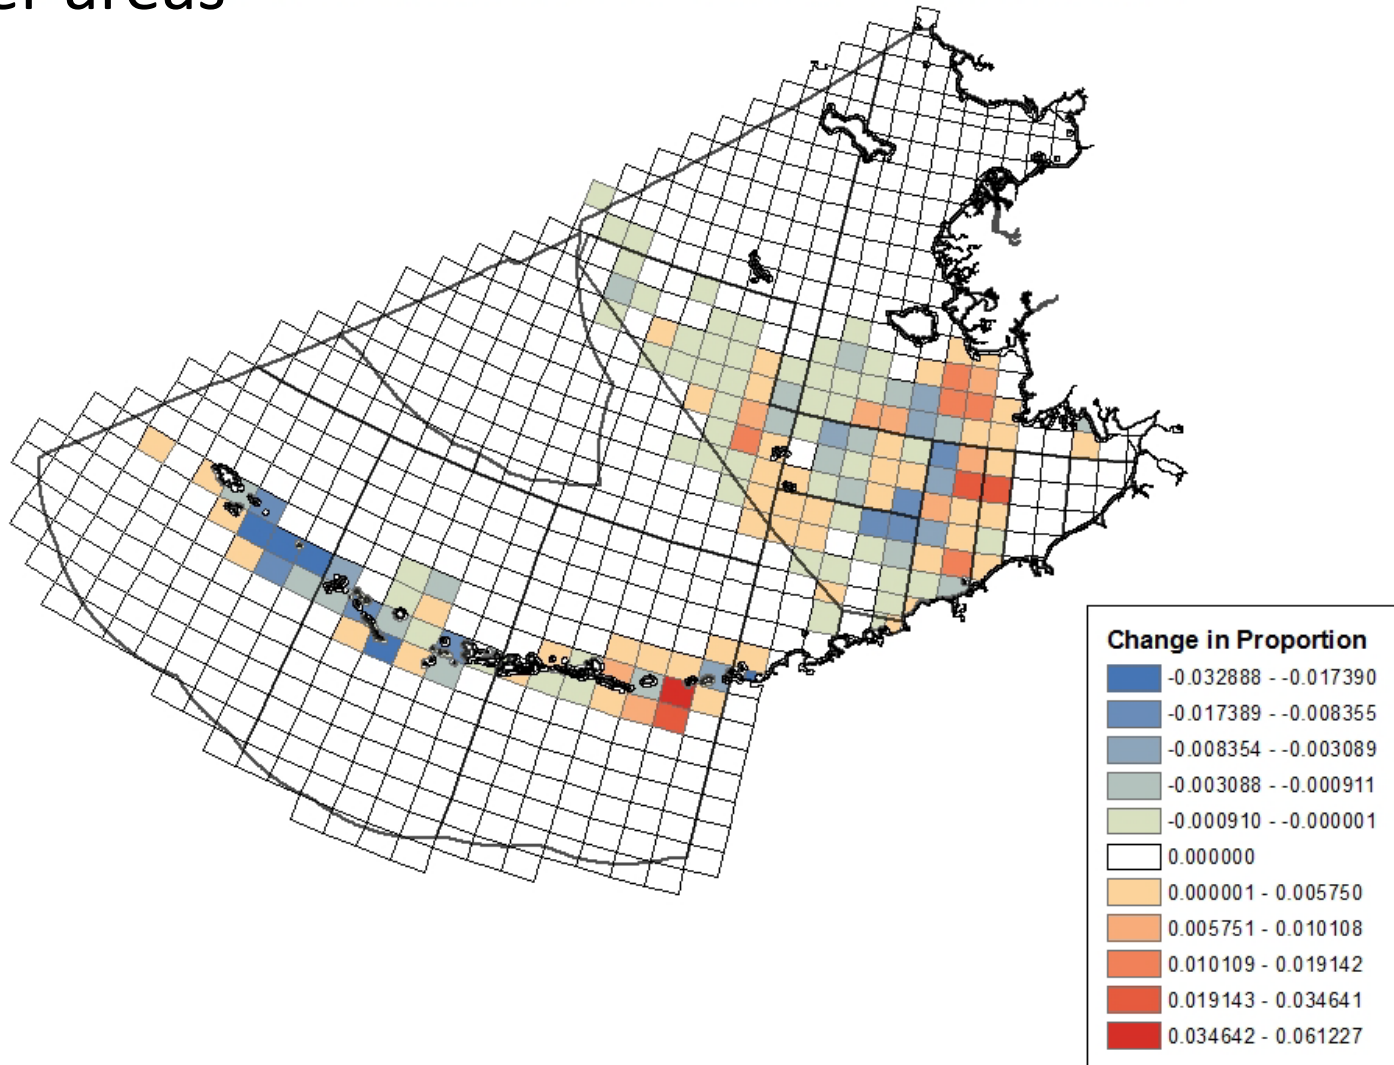

Little evidence of an effect: Why?

Substitution possibilities: “slack” in flatfish allocations

Little evidence of an effect: Why?

Substitution possibilities: mackerel and flatfish in other areas

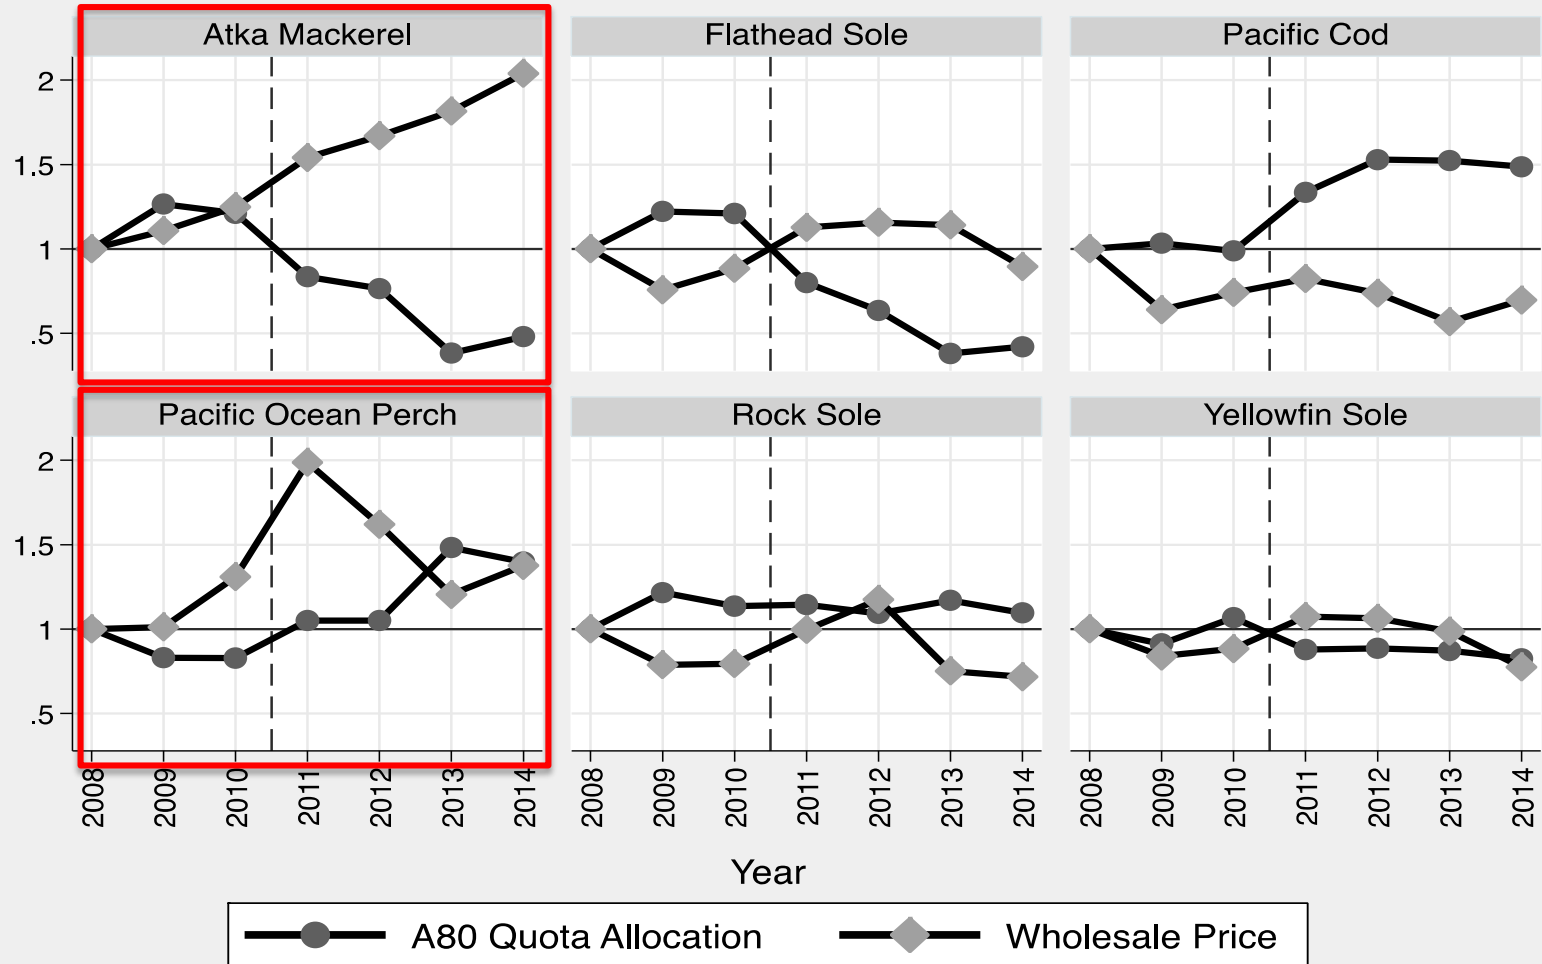

Little evidence of an effect: Why?

Challenges to identification: contamination/congestion

Little evidence of an effect: Why?

Challenges to identification: confounding factors

Note: quota allocations and wholesale prices measured relative to 2008

Little evidence of an effect: Why?

Challenges to identification: confounding factors

- SSL protective measures were not the only thing to happen in/after 2011:
 - Majority of the treated group formed a harvester cooperative in 2011
 - Protective measures closed more areas, but relaxed temporal restrictions in the small area that remained open
 - Years further away from intervention less likely to provide meaningful comparisons

Conclusion

- Little evidence of negative impact associated with SSL protective measures
 - Negative effects occur through higher costs, not forgone revenue
- SCM results indicate heterogeneous effects, but largely consistent with diff-in-diff
- Lack of effect likely due to substitution possibilities of fleet—slack in flatfish quota
- Costs associated with closures will be context specific, and will depend on other management institutions and substitution possibilities
