PRELIMINARY RESULTS OF SEEDLING DAMAGE
SURVEYS IN YOUNG PLANTATIONS ON SELECTED
FORESTS IN REGION 1

By

John Hard, Entomologist
and
John Rice, Biological Technician

INTRODUCTION

Based on per acre costs, plantation establishment is one of the most expensive silvicultural practices (Pfister 1976), but only token studies have been done on frequency and causes of seedling injury and mortality in Region 1 plantations (Wellner 1976). Therefore, we conducted a survey in 1978 on four National Forests to document frequency and causes of seedling injury or mortality in young plantations and to show land managers where plantation pest management might be desirable.

METHODS

We selected the Clearwater and the Nezperce National Forests in Idaho and the Lolo and Flathead National Forests in Montana to survey injury of planted seedlings. We were primarily concerned with plantations within the Douglas-fir, grand fir, and redcedar habitats that contained Douglas-fir, ponderosa pine, lodgepole pine, western larch, or Engelmann spruce seedlings planted between 1974 and 1978, but examined several plantations on the Clearwater National Forest that contained western white pine seedlings.

Plantations selected for examination were identified using Ranger District compartment records and were located on aerial photos before they were visited. Straight line transects intersecting a variety of topographic conditions, aspects, elevations, physiographic positions, and proximity to adjacent stands were traversed in each plantation. Circular 1/100-acre (radius = 11.8 ft.) sample plots located at equidistant intervals on each transect were examined, and each planted seedling was recorded by species and condition on a plot sample form (appendix).

RESULTS

Average stocking levels in surveyed plantations were low compared to desired stocking levels (table 1), but we do not know original stocking levels. A probable contributor to low stocking levels is gopher-caused seedling loss. However, this survey was not designed to reveal such loss because gophers often pull seedlings into their burrows, thus eliminating evidence of damage.

One-half to three-quarters of all seedlings examined, depending on species, were undisturbed (table 2). When considering all species and all forests combined, browsing by domestic stock or big game animals, and defoliation by insects each accounted for 6 percent of all examined seedlings, or 19 percent of all injured seedlings. Trampling by domestic stock or big game animals was the next most common cause of injury, and accounted for 4 percent of all examined seedlings, or 12 percent of all injured seedlings. Since domestic stock and big game are responsible for both browsing and trampling of seedlings, and injured 31 percent of all injured seedlings, we conclude that they are the most destructive agent to young planted seedlings in the four National Forests surveyed, especially on the Nezperce National Forest where over 50 percent of injured seedlings were trampled or browsed.

Defoliation, primarily by the western spruce budworm and the larch case-bearer, occurred on 20 percent of all grand fir seedlings, 15 percent of western larch seedlings, 7 percent of Douglas-fir seedlings, and 4 percent of Engelmann spruce seedlings (table 2). Defoliation was more common on the Clearwater and Lolo Forests than on the Nezperce and Flathead Forests.

Frost damage was most prevalent on the Flathead Forest, but was found extensively in only two Douglas-fir and Engelmann spruce plantations that had been established in natural frost pockets.

The western pine-shoot borer, a pine regeneration pest that mines the pith of terminal and lateral shoots, was found extensively in only one ponderosa pine plantation on the Nezperce Forest. This species can cause substantial reduction in height growth, but is probably a greater pest on seedlings older than 5 years.

Table 1.--Summary of areas examined in 1978 Plantation damage survey and percent stocking levels.

Forest	Ranger Districts	No. of plantations surveyed	Plantation acreages	No. of 1/100-acre plots	No. of seedlings observed	Expected No. of seedlings	% stocking ($\frac{\text{obs.}}{\text{exp.}} \times 100$)

1/ Based on a desired average of 400 seedlings planted per acre; personal communication, Pete Laird, Regional Silviculturist.

2/ Lost time due to a vehicle accident prevented the field crew from sampling this District more extensively.
