**Strophatrypa**, a new genus of Brachiopoda (Atrypidae), from upper Silurian strata of the Alexander terrane, Southeast Alaska

ARTHUR J. BOUCOT, ROBERT B. BLODGETT & DAVID M. ROHR

The atrypid brachiopod *Strophatrypa skaflestadi* gen. et sp. nov. occurs in unnamed upper Silurian strata exposed near the town of Hoonah on northeast Chichagof Island, Southeast Alaska. The new genus represents the first strophic atrypoid with many characters otherwise similar to those of the Atrypidae. Although this genus is known from only a single bed at one Alaskan locality, its unique morphology is worth noting in anticipation that similar forms may be discovered elsewhere in the Alexander terrane, or especially somewhere in Siberia where other taxa restricted to the Silurian of the Alexander terrane are shared. This paper represents a further contribution to our limited knowledge of the Silurian brachiopods of the Alexander terrane of Southeast Alaska. Key words: Brachiopoda, late Silurian, new genus, Alexander terrane, Southeast Alaska, U.S.A., palaeoecology, slope facies, palaeogeography.

Rohr, Department of Earth and Physical Sciences, Sul Ross State University, Alpine, Texas 79832, U.S.A.; drohr@sulross.edu

The present paper describes a new brachiopod genus and species, *Strophatrypa skaflestadi*, found in an unnamed Silurian unit of mixed siliciclastics and limestones exposed in and around the town of Hoonah, situated on the northeast part of Chichagof Island. It was discovered and collected by R.B. Blodgett, D.M. Rohr, and J.E. Skaflestad on July 30, 2010 in the north side of a small quarry (Fig. 1) about 1 km east of Hoonah Airport runway on Chichagof Island, southeast-Alaska, U.S.A. (locality 10RB10 – Latitude 58°05.716' N, Longitude 135°23.152' W). The quarry is reached by a small short road leading from the west from Forest Service Road 8052, the main road leaving and heading south of the town of Hoonah. The quarry is situated in the NW1/4 of the SE1/4 of section 35, T. 43 S., R. 62 E., Juneau A-5 1:63,360 scale quadrangle (Map edition 1994). The source quarry exposes two separate stratigraphic intervals: a lower greenish-gray, medium-bedded siltstone interval which forms the base of the quarry, and an upper limestone interval which forms cliffs on the south and west side of the quarry. The fossil-rich part (field locality 10RB10) of the siltstone beds is exposed on the north side of quarry (near NE end of quarry). The siltstone beds near the fossil locality strike N-S and dip steeply 70–75° to the west. This rich shelly fauna consists primarily of brachiopods along with a lesser amount of gastropods and bivalves (see Kříž et al. 2011 for description of the bivalves from this horizon). The fossiliferous zone which yielded this fauna was the only easily visible fossil-rich part of the siltstone beds exposed in the quarry. The age of this fossil horizon was indicated to be late Wenlock or early Ludlow according to the associated bivalve fauna (Kříž et al. 2011). The brachiopod fauna found here indicates only a generalized late Silurian age, and occurs primarily as disarticulated external and internal moulds extracted from siltstones. A limestone sample collected by D.M. Rohr in 2010 from the overlying limestone interval in the quarry was submitted to Ladislav Slavík (Praha, Czech Republic) who acidized the sample to extract conodonts. Unfortunately the sample proved to be barren. A sample of siltstone from the brachiopod-rich horizon was also unsuccessfully examined for chitinozoans by Viivi Nestor (Tallinn, Estonia).

This paper represents a further contribution to our limited knowledge of the Silurian brachiopods of the Alexander terrane of Southeast Alaska. Previous works dealing with Silurian brachiopods of this terrane include Kirk
(1922, 1925, 1926), Kirk & Amsden (1952), and Savage (1989) on faunas found to the south on the western side of Prince of Wales Island and its westerly adjoining smaller islands. These faunas are from shallow-water platform carbonate facies rocks and are richly endowed with large pentameroid brachiopods [i.e., Kirkidium, Brooksina, Harpidium, and Cymbidium]. The Chichagof Island brachiopod fauna represents a deeper-water, upper slope facies with a somewhat differing fauna, notably lacking in large pentameroids.

Geological setting

Palaeozoic rocks are exposed throughout much of the north-east part of Chichagof Island of Southeast Alaska, however, little is known of its Palaeozoic fauna and flora. The only publications providing formal descriptions of Palaeozoic fossils are two papers on Silurian bivalves. Kirk (1927a) who described and illustrated Pycinodesma benjamiini (Kirk), under the genus name Pycnodesma, which he later changed (Kirk 1927b) to Pycinodesma upon learning that the genus name was pre-occupied. This particular species was found in exposures of the type section of the Kennel Creek Limestone on the southern side of Freshwater Bay (Fig. 1). The other paper, Kříž et al. (2011), described a new bivalve community (Goniophora thula-Myttilarca boucoti Community) composed of 9 species from the same locality as Strophatrypa.

Geologic maps covering all or parts of Chichagof Island include Lathram et al. (1958), Lathram et al. (1959), Loney et al. (1963a), Loney et al. (1963b) and Karl (1999). Much of the basic stratigraphic nomenclature for this part of the island was established by Loney et al. (1963b). On the geologic map of northeast Chichagof Island of Karl (1999), the area including the quarry from which this collection was made was shown as being part of the Devonian age Cedar Cove Formation. Our field study indicated that many of the rocks exposed in the immediate area of Hoonah do not belong to the Cedar Cove Formation as indicated on the map of Karl (1999), but rather belong to a new unnamed mixed siliciclastic/limestone lithostratigraphic unit bearing late Silurian age fauna, probably forming a shelf-to-basin transitional lithofacies which lay to the north of late Silurian carbonate platform rocks of the Kennel Creek Limestone (Rohr et al. 2011). The Kennel Creek Limestone was established by Loney et al. (1963b), who considered it to be Middle Devonian in age. The only significant fossils found in the latter unit are the bivalve Pycinodesma and amphiporid stromatoporoids. More recent studies in Southeast Alaska clearly indicate that Pycinodesma is of late Silurian age, as originally indicated by Kirk (1927a, b), and the Kennel Creek is now recognized to be late Silurian in age.

Carbonate platform facies of the Kennel Creek Limestone, as mentioned above, are well exposed to the south of Hoonah, most notably in and around Freshwater Bay. One of the nearest Kennel Creek quarry exposures to our
Palaeozoic strata of northeast Chichagof Island belong to the Alexander terrane (Fig. 2), a major tectonic element in Southeast Alaska, northwestern British Columbia, and southwestern Yukon Territory. This terrane along with many other terranes forms an accretionary complex of allochthonous terranes which characterize much of the Western Cordillera of North America. The Alexander terrane was one of the first terranes to be recognized in western North America (Berg et al. 1972, Jones et al. 1972). Recent palaeobiogeographic studies indicate that the Alexander terrane has a fauna most similar to Siberia (Blodgett et al. 2002, 2003, 2010; Pedder 2006), notably its eastern portion. This terrane most likely originated as a rifted block of the eastern Siberian palaeocontinent, probably breaking away in the latter part of the Devonian (Blodgett et al. 2010).

Silurian shelly faunas of the Alexander terrane are distinctly different from those found along the western margin of cratonic North America. These differences are especially borne out by the gastropods (Rohr & Blodgett 2003, 2008; Rohr et al. 2003, 2008), brachiopods (Blodgett & Boucot 2009; Blodgett et al. 2002, 2010) and calcareous sponges (Rigby et al. 1994) found in Silurian strata of Alexander terrane. Summary data on the palaeobiogeographic affinities of the major Siluro-Devonian megafossil groups found in the Alexander terrane can be found in Blodgett et al. (2010). This latter study clearly shows the strongest palaeobiogeographic affinities are consistently found to be with the Siberian palaeocontinent. On-going studies of the Silurian brachiopods (by A.J. Boucot & R.B. Blodgett) and bivalves (by J. Klfi) will presumably throw additional light on this issue.

The fossil horizon containing *Strophatrypa skaflestadi* gen. et sp. nov. is a tan-weathering, greenish-gray, medium-bedded calcareous siltstone. Fine-sand to silt-sized grains of angular quartz, plagioclase and chert, minor detrital mica and glauconite are present. The fauna of this locality consists of a rich shelly benthos, especially brachiopods, but secondarily followed by bivalves and gastropods. Cephalopods are rare, favositid tabulate corals are also present, but form only a very minor component. Brachiopods retain shell microstructure, and they show little evidence of micritized rims indicating deposition below the photic zone (Filügel 2004). The brachiopods from this horizon were for the most part disarticulated, with the exception of a minority of the isorhizids and *Strophatrypa skaflestadi* gen. et sp. nov. which remain articulated. The high degree of disarticulation suggests a moderately high-energy setting, consistent with our interpretation of moderate transport (but not for great distances) on an inclined shelf to slope transition.

**Systematic palaeontology**

Order Atrypida Rzhonsnitskaya, 1960  
Suborder Atrypidina Moore, 1952  
Superfamily Atrypoidea Gill, 1871  
Family Atrypidae Gill, 1871  
Subfamily Atrypinae Gill, 1871  
Genus *Strophatrypa* gen. nov.

*Type species.*— *Strophatrypa skaflestadi* gen. et sp. nov. from unnamed upper Silurian strata south of the town of Hoonah, northeast Chichagof Island. The type specimens of *Strophatrypa skaflestadi* gen. et sp. nov., UAMES 14463–14476, are deposited at the University of Alaska Museum Eath Science Collection, Fairbanks.
Etymology. – Named to emphasize the strophic interareas, unusual for atrypoid brachiopods.

Diagnosis. – Atrypids with costellae that branch only at concentric growth lines, muscle field in both valves unimpressed, relatively small for the Family, and unique in having very narrow interareas in both valves, extending laterally almost to the maximum width.

Occurrence. – The new genus is known only from the Hoonah quarry locality, and as far as we know is restricted to the Alexander terrane of Southeast Alaska.

Description. – Impunctate, small to medium-size, unequally biconvex shells, with the dorsal valve less convex than the gently convex ventral valve, anterior commissure uniplicate, shells laterally elongate with rounded anterior and lateral margins, semicircular outline, greatest width near midlength, relatively broad, costellate dorsal sulcus and correspondingly broad, costellate ventral fold that have a regular change in slope into the lateral portions of the shell, ornamentation consists of well-marked concentric growth lines crossed by costellae that bifurcate at the first prominent growth line followed by additional bifurcations at more anterior growth lines. Form of deltidial region uncertain.

Ventral valve has two stout laterally broadening hinge teeth with an unimpressed muscle field. The external costellae are well marked interiorly. The dorsal valve has laterally directed, crenulated dental sockets, and a smooth area for diductor attachment, with an unimpressed muscle field, and anterior impressions of the external costellae. Spiralia and jugum unknown.

Comparison. – Lacks the comb-like ctenophoridium of Atrypa sensu stricti. Lacks any trace of dental lamellae, and has a wide, straight hinge line. Lacks the strongly impressed muscle fields present in most members of the Family. Differs from Dehelicteria by possession of prominent, concentric growth lamellae combined with coarser costellae. Has a strophic hinge line in contrast to Omnuta helia, as well as marked growth lines. Has a strophic hinge line and marked, concentric growth lines in contrast to Gotatrypa, as well as marked fold and sulcus and much lower level of valve convexity.

Diagnosis and description. – Because of monotypy, see that of genus.

Material. – 48 dorsal valves, 36 ventral valves, 4 articulated specimens.

Types. – Holotype, UAMES 14463, Fig. 3A, B; paratype, UAMES14464, Fig. 3C, D; paratype, UAMES 14465, Fig. 3E, F; paratype, UAMES 14466, Fig. 3G, H; paratype, UAMES 14467, Fig. 3I, J; paratype, UAMES 14468, Fig. 3K, L; paratype, UAMES 14469, Fig. 3M, N; paratype, UAMES 14470, Fig. 3O, P; paratype, UAMES 14471, Fig. 3Q; paratype, UAMES 14472, Fig. 4A, B; paratype, UAMES 14473, Fig. 4C, D; paratype, UAMES 14474, Fig. 4E, F; paratype, UAMES 14475, Fig. 4G, H; paratype, UAMES 14476, Fig. 4I, J.

Associated fauna. – The Hoonah late Silurian fauna is a relatively moderate diversity fauna with a dominance of brachiopods to be described subsequently [additional to Strophatrypa there are the following in moderate abundance: Howellella, Mesoleptostrophia, Isorthis (Arcualla), Morinorhynchus, “Atrypa”, together with a few valves of a pholidostrophid similar to Eopholidostrophia, several specimens of a gypidulid, a single specimen

Discussion. – Although this shell is known from only a single bed at one Alaskan locality its unique morphology is worth noting in the hope that similar forms will turn up elsewhere, especially somewhere in Siberia where other taxa restricted to the Silurian of the Alexander terrane are shared. No shells of this type are known from the late Silurian limestones and clastic rocks of Prince of Wales and Heceta Islands, suggesting that the Hoonah occurrence represents a different environment.

Strophatrypa skaflestadi sp. nov.

Acknowledgements

We are deeply indebted to Jeff E. Skaflestad of Hoonah, Alaska, who proved to be an excellent guide during our field work on Chichagof Island and led us to the quarry where the brachiopod described here was discovered. We wish to thank Valery V. Baranov (Yakutsk, Russia) for his helpful review of this paper.
