Beef Progeny Testing Report 1972-1973

Special Report 392
October 1973
Agricultural Experiment Station
Oregon State University, Corvallis

BEEF PROGENY TESTING REPORT
1972-1973

A. T. Ralston and T. P. Davidson

The interest in identification of genetically superior breeding stock continues to increase. The number of progeny tested has risen from 191 head in 1969-70 to 377 head in 1972-73.

The rations used were the same as those of past years and are shown in Table 1. The initial energy content of the ration was about 72% total digestible nutrients (TDN) and was changed to 75% TDN toward the end of the finishing period. The steers were implanted with 15 mg of diethylstilbestrol and the heifers with Synovex H.

The average daily gains were somewhat lower for this test period than we have experienced in the last two tests. This was primarily due to the weather conditions that tended to reduce gains in most feedlots throughout the west for that period. The reduction in liveweight per day of age and carcass weight per day of age were not of the same magnitude indicating either greater genetic potential, improved management prior to finishing or both (Table 2). A slow but consistent increase in initial test weight supports the previous statement.

Table 1. Progeny testing ration^a

Ingredients	to 650 lbs %	650-850 lbs %	850 lbs to slaughter %
Pelleted alfalfa	20.00	15.00	10.00
Beet pulp	7.00	10.00	10.00
Steam rolled barley	64.75	66.75	71.75
Trace mineralized salt	.75	.75	.75
Limestone	.50	.50	.50
Molasses	7.00	7.00	7.00

^aIn addition to the above, one pound of standard OSU 40% protein supplement was fed per head per day.

A. T. Ralston is professor of animal nutrition; T. P. Davidson is superintendent of the Umatilla Branch Experiment Station.

Table 2. Summary of four years progeny testing for average daily gains, liveweight per day of age and carcass weight per day of age.

Year	Average daily gain, 1b		Liveweight/day, 1b		Carcass weight/day, 1b	
	Heifers	Steers	Heifers	Steers	Heifers	Steers
1969	2.39	2.60	2.08	2.22	1.24	1.34
1970	2.42	2.67	2.22	2.31	1.32	1.41
1971	2.69	2.76	2.24	2.40	1.32	1.46
1972	2.38	2.56	2.15	2.34	1.33	1.42

The heifers had less intramuscular marbling, were of poorer conformation, had slightly less backfat and graded one third of a quality grade lower than the steers. This was due to much less time in the feedlot and perhaps the heifer progenies were not a true sample of the sires' potential as the better heifers are usually selected as replacements.

Although the steers were held to a heavier weight (1059) than in previous years, their intramuscular marbling and quality grade were not increased. There was an increase in outside fat which, coupled with slightly heavier carcasses and no increase in ribeye area, resulted in a sizable reduction in yield of estimated trimmed cuts.

Ten sires produced progeny that yielded 1.50 lbs of carcass per day of age. This is a very commendable growth rate when all things are considered.

Caution should be exercised when comparing a sires' potential value. The fact that his crossbred progeny do well may not indicate his true value due to the heterosis expressed by the crossbred calves.
