Report All Barberry

**Barberry Eradication** is a cooperative plant disease control project. Federal, state, county, and local agencies and individuals all have joined their efforts to locate and destroy all rust-spread ing barberry bushes. In some areas, seeds from planted bushes have been widely scattered by birds, and many barberry bushes are found growing wild. In these localities, crews of men make a careful inspection of all growth, including the tim ber along rivers and creeks and scattered brush patches in pastures, on hills, and along fence rows. In other localities, where conditions for barberry growth are not so favorable, only the inspection of farm and city plantings is necessary to locate the bushes.

Boys and girls and adults can help to reduce crop losses from stem rust by reporting locations of barberry bushes growing on their own or neighboring properties and in other places where they may be found growing wild. Information you give will help in two ways: (1) It will result in the removal of the bushes and thus reduce the possi bilities of rust losses in your own community; and (2) it will provide leads to other barberry bushes in your community and aid crews and fieldmen to complete their inspection work more quickly.

To report locations of rust-spreading barberry or for information concerning the project, consult your County Extension Agent.

Wheat from a Badly Rusted Field Compared with Normal Kernels from Healthy Plants

**Profit**

**Loss**

**Stem Rust (Red Stage) on Grain Stems**

**Rust-infected** barberry bushes are the important source of stem rust in the northwestern states. From these bushes, the disease spreads to nearby grains and grasses during May and June. If the weather is favorable, these local infection centers expand rapidly and result in extensive damage before crops ripen. Stem rust spreads from the barberry to grains and grasses and from field to field by tiny seedlike bodies called spores. These are windborne and function as "seeds" to start new food-sapping rust growths.

**Questions & Answers**

**What is Stem Rust?**

Stem rust is a disease of wheat, oats, barley, rye, and many grasses, caused by a tiny parasitic plant called a fungus. So called "red rust" and "black rust" refer to the different colors of the summer and fall overwintering spores of the stem rust.

**Does Weather Cause Stem Rust?**

Stem rust increases rapidly under warm, moist conditions and thrives especially in low spots and on lodged grain. However, the disease cannot occur unless spores of the rust fungus are present.

**Will Seed Treatment Control Stem Rust?**

Seed treatment aids in controlling smut and certain other cereal diseases, but has no effect on rust.

**Will Burning the Straw Control Stem Rust?**

No. It would be impracticable to attempt to burn all infected straw and grasses on which rust overwinters.

**Is Barberry the Only Shrub Known that Spreads Stem Rust?**

Only certain species of barberry harbor stem rust of grain. However, there are hundreds of different rusts, all with different life cycles, which attack a wide variety of plants.

**How Are Barberry Bushes Destroyed?**

Ammonium thiosulfate (convate) applied to the cut-off stems and crown is most commonly and safely used. Special formulations of 2,4-D also are effective with some varieties. Common stock salt, sodium chlorate, and kerosene are effective but should be used with caution. Digging is not recommended because of sprouting root fragments.

Wheat from a Badly Rusted Field Compared with Normal Kernels from Healthy Plants

PROFIT  LOSS

Stem Rust (Red Stage) on Grain Stems

STEM RUST is a major fungal disease of the small grain crops. The parasitic fungus attacks the stems and leaves of the grain plants and absorbs the food sap. The results is stunted, lightweight kernels and low yield and quality. In northern grain areas effective control is attained by destroying rust-susceptible barberry bushes. These are the alternate host plants to the disease and necessary for its seasonal development.

Questions & Answers

WHAT IS STEM RUST?

Stem rust is a disease of wheat, oats, barley, rye, and many grasses, caused by a tiny parasitic plant called a fungus. So called "red rust" and "black rust" refer to the different colors of the summer and fall overwintering spores of the stem rust.

DOES WEATHER CAUSE STEM RUST?

Stem rust increases rapidly under warm, moist conditions and thrives especially in low spots and on lodged grain. However, the disease cannot occur unless spores of the rust fungus are present.

WILL SEED TREATMENT CONTROL STEM RUST?

No. It would be impractical to attempt to burn all infected straw and grasses on which rust overwinters.

IS BARBERRY THE ONLY SHRUB KNOWN THAT SPREADS STEM RUST?

Only certain species of barberry harbor stem rust of grain. However, there are hundreds of different rusts, all with different life cycles, which attack a wide variety of plants.

HOW ARE BARBERRY BUSHES DESTROYED?

Ammonium sulfamate (ammate) applied to the cut-off stems and crowns is most commonly and safely used. Special formulations of 2,4-D also are effective with some varieties. Common stock salt, sodium chlorate, and kerosene are effective but should be used with caution. Digging is not recommended because of sprouting root fragments.

BARBERRY ERADICATION is an old and proved method of reducing losses caused by stem rust. As early as 1660, France passed laws prohibiting barberry bushes near grain fields. For many years, Denmark, Germany, Norway, England, and France have recognized the value of barberry eradication for rust control.

Barberry bushes were brought from Europe by America's early settlers. By 1700 grain was being grown on the pioneer farms of the northeastern states. By 1814, however, several states and the United States Department of Agriculture are cooperating in an extensive program of barberry eradication for stem rust control.

ALL RUST-SUSCEPTIBLE BARBERRY MUST GO

RUST-INFECTED barberry bushes are the important source of stem rust in the northwestern states. From these bushes, the disease spreads to nearby grains and grasses during May and June. If the weather is favorable, these local infection centers expand rapidly and result in extensive damage before crops ripen. Stem rust spreads from the barberry to grains and grasses and from field to field by tiny seedlike bodies called spores. These are windborne and function as "seeds" to start new food-sapping rust growths.

A Typical Common (Rust-Spreading) Barberry

Illustrations appearing in this bulletin are used by permission of the United States Department of Agriculture. Some of the cuts for illustrations were made in the courtesy of the Committee for the Prevention of Grain Rust, Minneapolis, Minnesota.
THE STEM RUST DISEASE is often referred to as "red" rust or "black" rust because of its reddish and black appearance at different seasons. Stem rust is caused by a small parasitic growth called a fungus, and therefore is an effective control measure for stem rust. These races that develop on barberry may attack previously rust-resistant grain varieties.

Barberry bushes are doubly dangerous: first, they enable rust to repeat its life cycle from year to year and thus continue the toll of crop damage; second, they enable new rust races to develop and thereby endanger new grain varieties.

The eradication of rust-susceptible barberry requires strict state and Federal regulations prohibiting the growing of rust-susceptible barberry or its transport across state lines. Barberry bushes grow in hedges and other landscaping purposes. These are the important facts at a glance: (1) Rust-susceptible barberries are the only shrubs that harbor stem rust. (2) A single barberry bush may produce more than 64 billion spores, which are carried by the wind. These infect grains and grasses and produce the rapidly multiplying red summer spores. (3) The red spores easily live over the winter. They can infect only susceptible barberry bushes the following spring. (4) New rust races that develop on barberry may attack previously rust-resistant grain varieties.

Facts to Remember

There are more than 200 known races of stem rust. These are designated by number and differ in their ability to attack varieties of small grain. Hybridization occurs only on the barberry. Do not confuse stem and leaf rust. Stem rust should not be confused with the leaf rusts that attack wheat, oats, barley, and rye, or the stripe rust of wheat. Although any of the rusts may be found on the stems and leaves, stem rust is primarily a disease of the stems, and the stripe and leaf rusts are predominantly diseases of the leaves. Although both types of rust develop and spread under similar conditions, they are entirely different. The barberry is the alternate host plant for stem rust only.

Weather and Stem Rust

Weather and moisture conditions are closely linked with rust development. The stem rust fungus is itself a simple form of plant life. The red summer spores that are produced as the fungus grows function similarly to the seeds of larger plants. Moist and warm conditions are necessary for the rapid germination of the spores and the subsequent growth of the fungus. With these favorable conditions, new generations of many thousands of rust spores may be produced every six to ten days.

Low, lodged, or damp areas in grain fields are damaged most by stem rust because of the rank growth and warm, humid conditions in these spots. Extended periods of summer rainfall also materially aid rust development. Stem rust does not develop spontaneously from wet conditions. The spores of the disease must be present before infection starts.

Japanese Barberry Harmless Do Not Destroy

The Japanese barberry (Berberis thunbergii), of both the red- and green-leaved varieties, is immune to stem rust. These non-invasive ornamental shrubs commonly grown for hedges and other landscaping purposes.
BARBERRY ERADICATION is a cooperative plant disease control project. Federal, state, county, and local agencies and individuals all have joined their efforts to locate and destroy all rust-spread ing barberry bushes. In some areas, seeds from planted bushes have been widely scattered by birds, and many barberry bushes are found growing wild. In these localities, crews of men make a careful inspection of all growth, including the timber along rivers and creeks and scattered brush patches in pastures, on hills, and along fence rows. In other localities, where conditions for barberry growth are not so favorable, only the inspection of farm and city plantings is necessary to locate the bushes.

Boys and girls and adults can help to reduce crop losses from stem rust by reporting locations of barberry bushes growing on their own or neighboring properties and in other places where they may be found growing wild. Information you give will help in two ways: (1) It will result in the removal of the bushes and thus reduce the possibilities of rust losses in your own community; and (2) it will provide leads to other barberry bushes in your community and aid crews and fieldmen to complete their inspection work more quickly.
