## ABSTRACT

Wecoma cruise W8705A was conducted in May 1987 as part of the pilot study for the Coastal Transition Zone project. CTD observations were made in the coastal transition zone off northern California between 37.5°N and 41.5°N. Strong winds (with speeds up to 35 kts) prevailed during the survey, but 98 stations were completed successfully. They were concentrated along three alongshore transects, at distances of 60, 90 and 150 km from the coast. Maximum sampling depth at most stations was 500 m. Temperature, salinity, light transmission and fluorescence were measured at all stations. This report presents vertical profile plots and tabulations of data at selected depths for each station; vertical sections of temperature, salinity and potential density anomaly ( $\sigma$ -theta) for the long alongshore and cross-shore sections; and maps of temperature, salinity, potential density anomaly and dynamic topography at selected depths.

## ACKNOWLEDGMENTS

We are grateful to all those who participated in this cruise, and particularly to the master, crew and the marine technicians of the R/V Wecoma for their expert work during the persistently rough weather on this cruise. Pat Collier assisted in the preparation of this report. This study is funded by the Office of Naval Research, contract number N00014-87-K-0242.

## INTRODUCTION

This was the second of three mapping cruises designed to determine the general character of the mesoscale flow field in the Coastal Transition Zone off northern California during the winter and late spring of 1987. All three cruises were intended to have the same basic sampling pattern (shown in Figure 1) covering an alongshore extent of about 450 km. The cruise track was designed to consist of three modular units (A,B, and C, south of Pt. St. George, Cape Mendocino and Pt. Arena, respectively), each of which would take about three days to complete, and thus provide a synoptic mesoscale survey of each unit. Each module included alongshore transects at about 90 and 150 km from shore, and cross-shore transects either (1) extending out 60 km from the coast or (2) connecting the alongshore transects. The combination of three modules yields two continuous alongshore sections (Lines I and II, 150 and 90 km from shore respectively) each about 450 km long, and a discontinuous alongshore transect about 60 km offshore. On each cruise, we planned to make closely spaced CTD casts to 500 m on the outer transects of the southern modules; it is in this region that seaward jets and narrow filaments of cold surface waters had been observed previously (Flament et al., 1985; Kosro and Huyer, 1986). On each cruise, we operated a 300 kHz acoustic-Doppler current profiler continuously and obtained continuous underway surface temperature and salinity data. Complementary biological observations were made on all three cruises by T. Cowles and L. Small of Oregon State University, R.T. Barber and F.A. Chavez of Duke University, and M. Abbott and R. Hood of Scripps Institution of Oceanography. Mark Abbott, Bob Whritner and Melissa Ciandro of the Scripps Satellite Facility provided transmission to the ship of sea surface temperature maps derived from the AVHRR sensor on the NOAA9 satellite. The CTD data from the February cruise have been presented in an

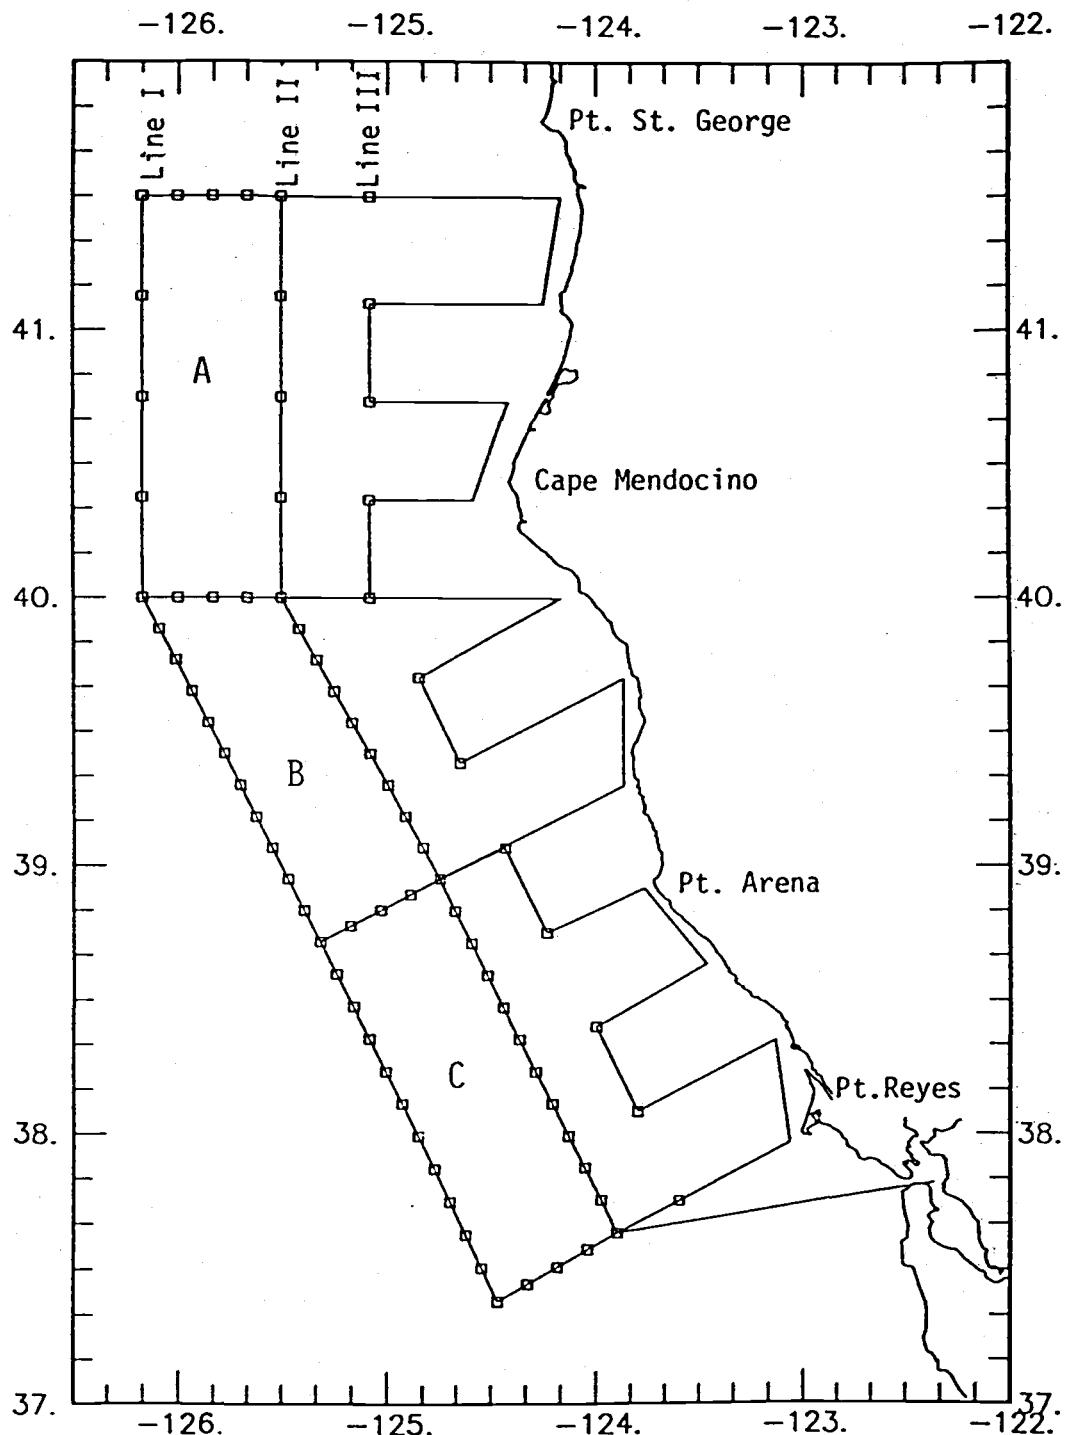

Figure 1. The basic sampling plan for the three CTZ mapping cruises in 1987. Actual sampling during each cruise varied from this pattern because of weather and other constraints.

earlier report (Schramm et al., 1987); this data report presents the CTD data from the May cruise.

The ship departed from San Francisco, California on the morning of 18 May 1987, and arrived at Station 1 at  $37^{\circ}38'N$ ,  $123^{\circ}54'W$  on the south side of Module C (Figure 2) at 2300 UT. Winds were favorable for coastal upwelling and increasing in strength from about 10 to 25 kts at this time (Figure 3). We worked offshore to Station 5 (Figure 2, Table 1) and then turned to work northwestward along Line I (Figures 1, 2). During 19 May, winds increased in strength to more than 30 kts, and by the end of Station 15 (near the northwest corner of Module C; Figure 2) it was too rough to continue CTD operations. We proceeded northeastward to intersect Line II at about  $39^{\circ}N$  and Line III at  $39^{\circ}10'N$ . Since it was still too rough to run sections perpendicular to the coast, we turned southeastward along Line III. By first light on 20 May the wind had dropped sufficiently (to 28 kts) to resume CTD operations with Station 16 (Table 1), and we continued to work southeastward along Line III to Station 20 (Figure 2). From Station 21 (at the same location as Station 1) we worked northwestward along Line II to Station 32. Since wind speeds had dropped to less than 20 kts, we turned offshore to complete the perimeter of the offshore rectangle of Module C with Stations 33-36, and then backtracked toward the coast to begin Module B.

On 22 May, Stations 37-40 were occupied on the southern inshore sections of Module B. Since the strong winds had caused us to be behind schedule, we continued northward along Line III rather than making the inshore sections at the northern end of Module B. At Station 42, we turned offshore along  $40^{\circ}00'N$  and worked to Station 47 at the northwest corner of Module B, and then worked southeastward along Line I to Station 58 at the southwestern corner of Module B. We repeated two stations along its southern boundary, and

then worked northwestward along Line II to complete Module B with Station 69 on 24 May.

We began work in Module C by continuing northward along Line II on 24 May. Preliminary CTD and ADCP data from Module B had indicated a strong, narrow current flowing onshore across Lines I and II just south of 40°N. We suspected there might be another strong narrow current flowing offshore in the southern portion of Module A, and therefore continued the close (14 km) spacing between CTD stations. Since brisk winds and rough seas were still prevalent, we decided to truncate Module A at 41°06'N (well after crossing the expected offshore-flowing jet), rather than continuing northward to 41°30'N as originally planned. In the expectation that we would again see the jet as a southward current, we turned toward shore, following station 78. We completed two inshore sections in Module A, and then proceeded southward along Line III, occupying Stations 82-84. A few stations along 40°00'N were repeated and another closely-spaced alongshore section was completed along Line I. This section, too, showed a strong narrow current flowing offshore on the north side of the Mendocino Ridge. Stations 96-98 closed the offshore rectangle of Module A, and CTD operations were suspended at about 1300 UT on 26 May. To obtain additional ADCP and surface temperature and salinity data across the pair of jets near 40°N, we proceeded southward along Line II to 39°10'N. We then turned inshore to collect underway data along a line about 12 nm inshore of Line III in order to partially fill the gap left in Module C. The ship returned to San Francisco at about 1600 UT on 27 May.

Personnel participating in the cruise were Michael Kosro (chief scientist), Adriana Huyer, Tim Cowles, Rich Schramm, Jane Fleischbein, Henry Pittock, Pat Collier, Ted Benson, Nan Dudek and Kevin Krefft of Oregon State University; Francisco Chavez and Patrick Whaling of Duke University; Robert

Petty of UC Santa Barbara; and Raleigh Hood and Victoria Cowles of Scripps Institution of Oceanography.

#### SAMPLING AND CALIBRATION PROCEDURES

A Neil Brown Instruments Mark IIIb conductivity-temperature depth (CTD) probe (#2561) was used to obtain continuous profiles of temperature and salinity and pressure at each station. The profiling package consisted of the CTD mounted below a General Oceanics Rosette sampler with twelve 5 liter Niskin bottles. Mounted adjacent to the CTD were a Sea Tech 25 cm transmissometer (s/n 33D) and a Sea Tech Fluorometer (s/n 27). The CTD was fitted with a 1600 decibar pressure sensor. The fast response thermistor was disabled and replaced in the circuitry with a precision 10 ohm resistor to permit only the platinum thermometer's temperature signal to be digitized. The time constant of the platinum resistance thermometer of the probe had earlier been determined to be 0.235 sec (Fleischbein et al., 1987) using estimates of the slope of the phase spectrum between the measured temperature and conductivity as suggested by Millard, Toole and Swartz (1980). The CTD was set to sample at its maximum rate of 32 Hz. The entire instrument package was lowered at a rate of about 45 meters per minute to a depth of 500 decibars.

OSU's CTD probe #2561 was calibrated for pressure, temperature and conductivity by the manufacturer in December 1986. Previous experience has indicated that the CTD pressure and temperature sensors are very stable over a period of several months: temperature to within a few millidegrees and pressure to within a few decibars. At a few stations, protected reversing thermometers were mounted on one bottle; these thermometers are calibrated once every three years at the Northwest Regional Calibration Center and have

an accuracy of  $\pm 0.02^{\circ}\text{C}$ . The temperatures recorded by these thermometers were the same as the CTD temperature within the stated accuracy of the reversing thermometers. The CTD temperature sensor was calibrated in the laboratory at OSU in August 1987; results of that calibration (mean difference less than  $0.001^{\circ}\text{C}$  from the standard) confirmed that no correction was needed. The CTD pressure at the surface prior to a cast was recorded at regular intervals during the cruise; it always remained less than 0.5 dbar which is within the stated accuracy of the pressure sensor ( $\pm 1.6$  dbar) so no correction was applied to the CTD pressure data.

The CTD conductivity calibration can vary considerably with time, even over a few weeks or months. Normally the conductivity calibration is expressed as a multiplier to the raw conductivity; if the overall conductivity range is very small (as in the upper 500 m off northern California) an additive correction may be used instead. No CTD conductivity correction was required for the February cruise (Schramm et al, 1987), but the conductivity cell used in February failed on a subsequent cruise and was replaced prior to W8705A. The replacement cell had not been used or calibrated in several years. We collected water samples at each station from Niskin bottles at selected depths to provide in situ conductivity calibration data. Bottles were tripped during the up-cast, and the CTD data to be compared with the samples were recorded at the actual depth at which each bottle was tripped. Duplicate salinity samples were drawn from selected bottles and stored in round 4-oz. glass bottles with new poly-seal caps, with an additional outer seal of 'Parafilm'. One complete set of the salinity samples was analyzed on a Guildline 8400A Autosal salinometer (OSU's #3) after the ship returned to Newport (i.e., during late June and July 1987). Duplicates were analyzed mainly to check those sample values which showed

relatively large differences from the CTD. The Guildline Autosal determines water sample salinity with a precision of  $\pm 0.002$  and an accuracy of  $\pm 0.003$ . Sample conductivities were calculated using the sample salinity value with the CTD temperature and pressure values; a value of  $42.914 \text{ mmho cm}^{-1}$  for the conductivity of standard seawater at  $15^\circ\text{C}$  (Culkin and Smith, 1980) was used to convert the measured sample conductivity ratios to conductivity. Sample conductivities were compared to CTD conductivities which had been corrected for temperature and pressure effects on the cell. Ten out of 210 CTD-sample differences were much larger than the others, as large as several standard deviations; these occurred in regions of sharp vertical gradients and were eliminated from the in situ calibration data set. The remaining sample conductivity values indicate there was a definite trend in the CTD calibration during the first half of the cruise, with conductivity differences gradually decreasing from about  $0.014 \text{ mmho cm}^{-2}$  at the first station to about  $0.004 \text{ mmho cm}^{-2}$  at Station 49. During the last half of the cruise, the calibration remained steady. Thus the data from the cruise was divided into two parts to determine the appropriate CTD conductivity correction: Stations 1-49, and Stations 50-98. A least-squares fit to the conductivity differences from the first group yielded the equation:

$$C = C_0 - 0.0131 + 0.000194 N$$

where  $C$  is the corrected conductivity,  $C_0$  is the raw conductivity data, and  $N$  is the consecutive station number (between 1 and 49). Applying this correction resulted in small conductivity differences (Table 2) with a mean of zero and a standard deviation of  $0.0024 \text{ mmho cm}^{-2}$ . There was no definite trend during the second half of the cruise; the mean conductivity difference for Stations 50-98 was 0.0028 and the standard deviation was  $0.003 \text{ mmho cm}^{-2}$ .

Table 2. Results of *in situ* calibration samples, W8705A Stations 1-49: station number, sample depth (Z), additive conductivity correction for CTD data (DLC), and the comparison between sample and corrected CTD values of temperature (T), conductivity (C) and salinity (S).

Thus for these stations the CTD conductivity was corrected according to the equation :

$$C = C_0 - 0.0028$$

where  $C$  is the corrected conductivity and  $C_0$  is the raw conductivity.

Applying this correction resulted in differences with a mean of zero and a standard deviation of 0.0026 mmho cm<sup>-2</sup> (Table 3).

The transmissometer measures the light transmitted by a collimated beam of nearly monochromatic (660 nm) light through a path length of 25 cm. It provides an analog output of 0 to 5 VDC, corresponding to 0 to 100 % transmission. This output is digitized by the CTD using the full integer range of 0 to 4095, and merged into the data stream. Prior to the cruise, the manufacturer calibrated the transmissometer against a distilled water standard. Readings in air were also obtained at this time for comparison with readings in air obtained during the cruise. The results are used to correct the measured voltage using the formula:

$$\text{VOLTS} = (\text{AIROLD}/\text{AIRNEW}) * (\text{TVOLT-ZERO})$$

where VOLTS is the corrected voltage, AIROLD is the voltage output in air obtained during the precalibration (4.741 V in this case), AIRNEW is the voltage output obtained in air during the cruise (4.738 V in this case), TVOLT is the measured voltage output, and ZERO is the voltage output when the light path is completely blocked (0.0007 V in this case). The formula

$$\text{TRANS} = (\text{VOLTS}/5)*100.$$

was used to convert the corrected voltage to percent transmission.

The fluorometer measures the fluorescence emitted by photosynthetic pigments (chlorophyll and related pigments) in marine phytoplankton following excitation with blue light from a xenon flashlamp. The fluorometer provides analog output of 0 to 5 VDC, with adjustable sensitivity ranges and integration time constants. The fluorometer was operated at a mid-range

Table 3. Results of in situ calibration samples from W8705A Stations 50-98: comparison between sample and corrected CTD values of temperature (T), conductivity (C), and salinity (S). CTD values have been corrected by subtracting 0.0028 mmho cm<sup>-2</sup> from the raw conductivity data.

setting which provided an operational sensitivity range of approximately 0.2 to 8.0  $\mu\text{g}$  pigment per liter. The analog output is digitized by the CTD and merged into the data stream. Calibration samples from multiple depths were obtained via rosette samples from over 50 stations per cruise. *In vivo* fluorescence values from the fluorometer were compared with the extracted pigment concentrations obtained from the calibration samples, using standard chlorophyll extraction techniques for frozen, filtered samples. The calibration resulted in the following conversions for the voltages reported in this report, with  $r$ , the correlation coefficient, shown for each result:

May-Day (0630-1900 local time (GMT-7))

upper 50 meters

$$\begin{aligned} \text{total pigment} &= 1.06 * \text{volts} + 0.35 & r &= .73 \\ (n = 105) & & & \end{aligned}$$

$$\begin{aligned} \text{chlorophyll a} &= 0.83 * \text{volts} + 0.26 & r &= .69 \\ (n = 105) & & & \end{aligned}$$

below 50 meters

$$\begin{aligned} \text{total pigment} &= 0.57 * \text{volts} + 0.56 & r &= .59 \\ (n = 23) & & & \end{aligned}$$

$$\begin{aligned} \text{chlorophyll a} &= 0.48 * \text{volts} + 0.27 & r &= .69 \\ (n = 23) & & & \end{aligned}$$

May-Night (1900-0630 local time (GMT-7))

upper 50 meters

$$\begin{aligned} \text{total pigment} &= 0.90 * \text{volts} + 0.24 & r &= .76 \\ (n = 93) & & & \end{aligned}$$

$$\begin{aligned} \text{chlorophyll a} &= 0.71 * \text{volts} + 0.13 & r &= .77 \\ (n = 93) & & & \end{aligned}$$

below 50 meters

$$\begin{aligned} \text{total pigment} &= 0.63 * \text{volts} + 0.20 & r &= .60 \\ (n = 15) & & & \end{aligned}$$

$$\begin{aligned} \text{chlorophyll a} &= 0.50 * \text{volts} + 0.06 & r &= .61 \\ (n = 15) & & & \end{aligned}$$

The poor correlations below 50 meters are the consequence of degradation of

photosynthetic pigments via the grazing processes of zooplankton. The in situ chlorophyll values at 5 meters are shown in Figure 4.

#### CTD DATA PROCESSING PROCEDURES

The CTD data are recorded at sea on a Kennedy 9-track data logger, with many stations on each tape. Data logging normally begins as soon as the CTD probe is in the water, and continues until after the probe has reached the maximum depth. The first step in data processing is to obtain a directory of the data tape using program NBCTD3. For each station, this directory lists the header data, the block number in which the instrument descent begins, and the maximum pressure. NBCTD3 is then used to create disc files of pressure, temperature, conductivity and transmissometer counts for each cast. This program also corrects the conductivity data for variations in cell geometry due to pressure and temperature changes. Using program CTDRED6 we then apply the temperature, conductivity and pressure calibrations (described above), and check for extraneous values and extreme gradients. This program applies a recursive filter designed by R. Millard (S. Hayes, pers. comm.) to the conductivity data to remove the phase difference introduced by the finite response time ( $T = 235$  msec) of the temperature sensor; this filter has the form

$$C(n) = a_o C(n-1) + (1-a_o) C_i(n)$$

where  $C_i(n)$  is the observed value plus the calibration adjustment,  $C(n)$  is the filtered value of the  $n^{\text{th}}$  scan, and  $a_o = T / (T + t_i) = 0.880$  is a constant determined from the time constant  $T$  and the time interval  $t_i$  between scans. The same recursive filter is applied to the pressure data to reduce the digitizing noise and ensure that the pressure data is in phase with the

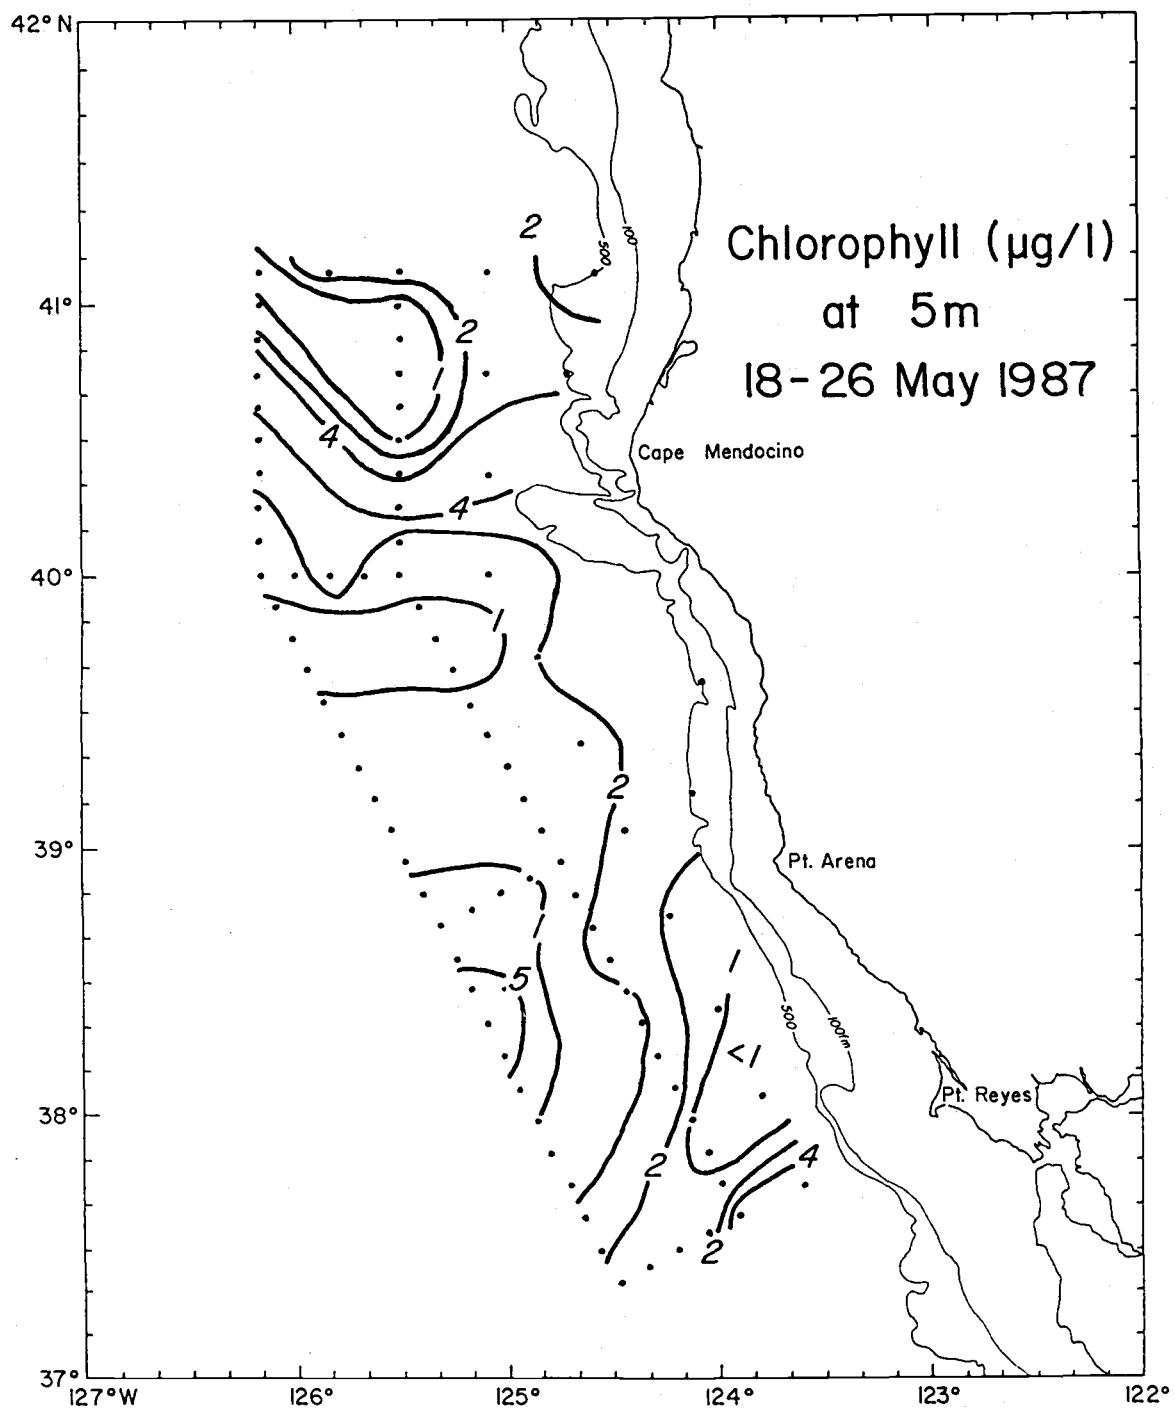

Figure 4. Map of in situ chlorophyll ( $\mu\text{g/l}$ ) at 5 m, 18 - 26 May 1987.

temperature and conductivity data at low frequencies (<1 Hz). Practical salinity (Lewis, 1978) is computed from the temperature and the filtered conductivity and pressure data using standard algorithms (Fofonoff and Millard, 1983) and a value of 42.914 to convert CTD conductivity to conductivity ratio (Culkin and Smith, 1980).

The filtered pressure data are used to eliminate the ascending scans caused by ship's motion. Data collected during descent are sorted into 2 dbar bins, and the extremes and averages of each variable are computed for each bin. Profiles of the temperature and salinity extremes are plotted to determine whether further editing is needed, and the 2 dbar mean temperatures and salinities constitute the processed data. When editing appears to be necessary, the original data files are examined in detail; data points that are rejected are replaced by linearly interpolated values, and the files are reprocessed using CTDRED6.

During cruise W8705A a loose connection inside of the transmissometer caused intermittent voltage drops in the transmissometer power. Due to the infrequency and short duration of the voltage drops, the problem was not detected until Station 74. The problem would cause the transmissometer data to drop suddenly to a value of zero within a few frames of data and then to slowly return from zero to near its original value again after some period of time, typically within one second (32 frames). The transmissometer was successfully repaired during Station 77. Altogether 39 stations were affected by the problem during the period of time covered by Station 6 through 76.

To remove the spikes caused by the voltage dropouts, the raw, unfiltered data files from program NBCTD3 were pre-processed through a program called TRAN2. In this program, the first 100 frames of data were accepted as given.

From this point each successive frame's transmissometer value was compared to the running average and standard deviation of the preceding five frames of data. If the data value was less than the running mean minus ten counts or less than the running mean minus ten standard deviations, then the data was set to a value of -88 to indicate an off-scale condition. In addition, if the data value was zero, a flag was set to indicate to the program that a voltage drop had occurred. In this case, data would continue to be set to -88 until the transmissometer value had returned to within 2.5 standard deviations or 2 counts (whichever was greater) of the mean.

The output file from TRAN2 was then run through a modified version of program CTDRED6 (CTDRED8) which ignored values of -88 when computing the average transmissometer values for each depth bin. If all of the data within a bin were -88, then the transmissometer output for that bin was set to -88. Otherwise the value retained was the average of all of the on-scale (greater than zero) points within a bin.

The processed data files containing integral pressure, and average temperature, conductivity, salinity, transmission, etc., are archived. These files are used to calculate other parameters of interest such as potential temperature ( $\theta$ ), potential density anomaly ( $\sigma-\theta$ ), specific volume anomaly, geopotential anomaly, sound velocity, etc., from the new equation of state of sea-water (UNESCO, 1981) using standard algorithms (Fofonoff and Millard, 1983). In this data report we show only profile plots of temperature, salinity,  $\sigma-\theta$ , fluorescence voltage and light transmission vs. pressure, and tables of temperature, salinity,  $\sigma-\theta$ , specific volume anomaly, geopotential anomaly, light transmission and fluorescence voltage at selected pressures.

## DATA PRESENTATION

The hydrographic data are summarized in maps, vertical sections, and profile plots. For each alongshore and cross-shore section, we show the vertical distribution of temperature, salinity and sigma-theta, contoured subjectively. Tick marks at the top of each section indicate station positions at which a CTD cast was made.

For the complete survey, we show maps of temperature, salinity and sigma-theta at eleven standard depths: 0, 25, 50, 75, 100, 150, 200, 250, 300, 400 and 500 db. Maps of dynamic heights of the sea surface relative to 50, 100, 200 and 500 db, of the 25, 50 and 100 db surfaces relative to 250 db; and of the 25, 50, 100, 150 and 200 db surfaces relative to 500 db are included. All of the maps were contoured subjectively.

Averages and standard deviations of the profiles of temperature, salinity and sigma-theta vs pressure are presented for each module (Figure 5) and for each alongshore transect (Figure 6). The average and standard deviations for the temperature vs salinity curve are also shown (Figure 7).

Vertical profiles of temperature, salinity and sigma-theta vs. pressure are presented for the 98 stations. In addition, a second plot shows the vertical profiles of light transmission and fluorescence with the salinity profile repeated to facilitate comparisons among variables.

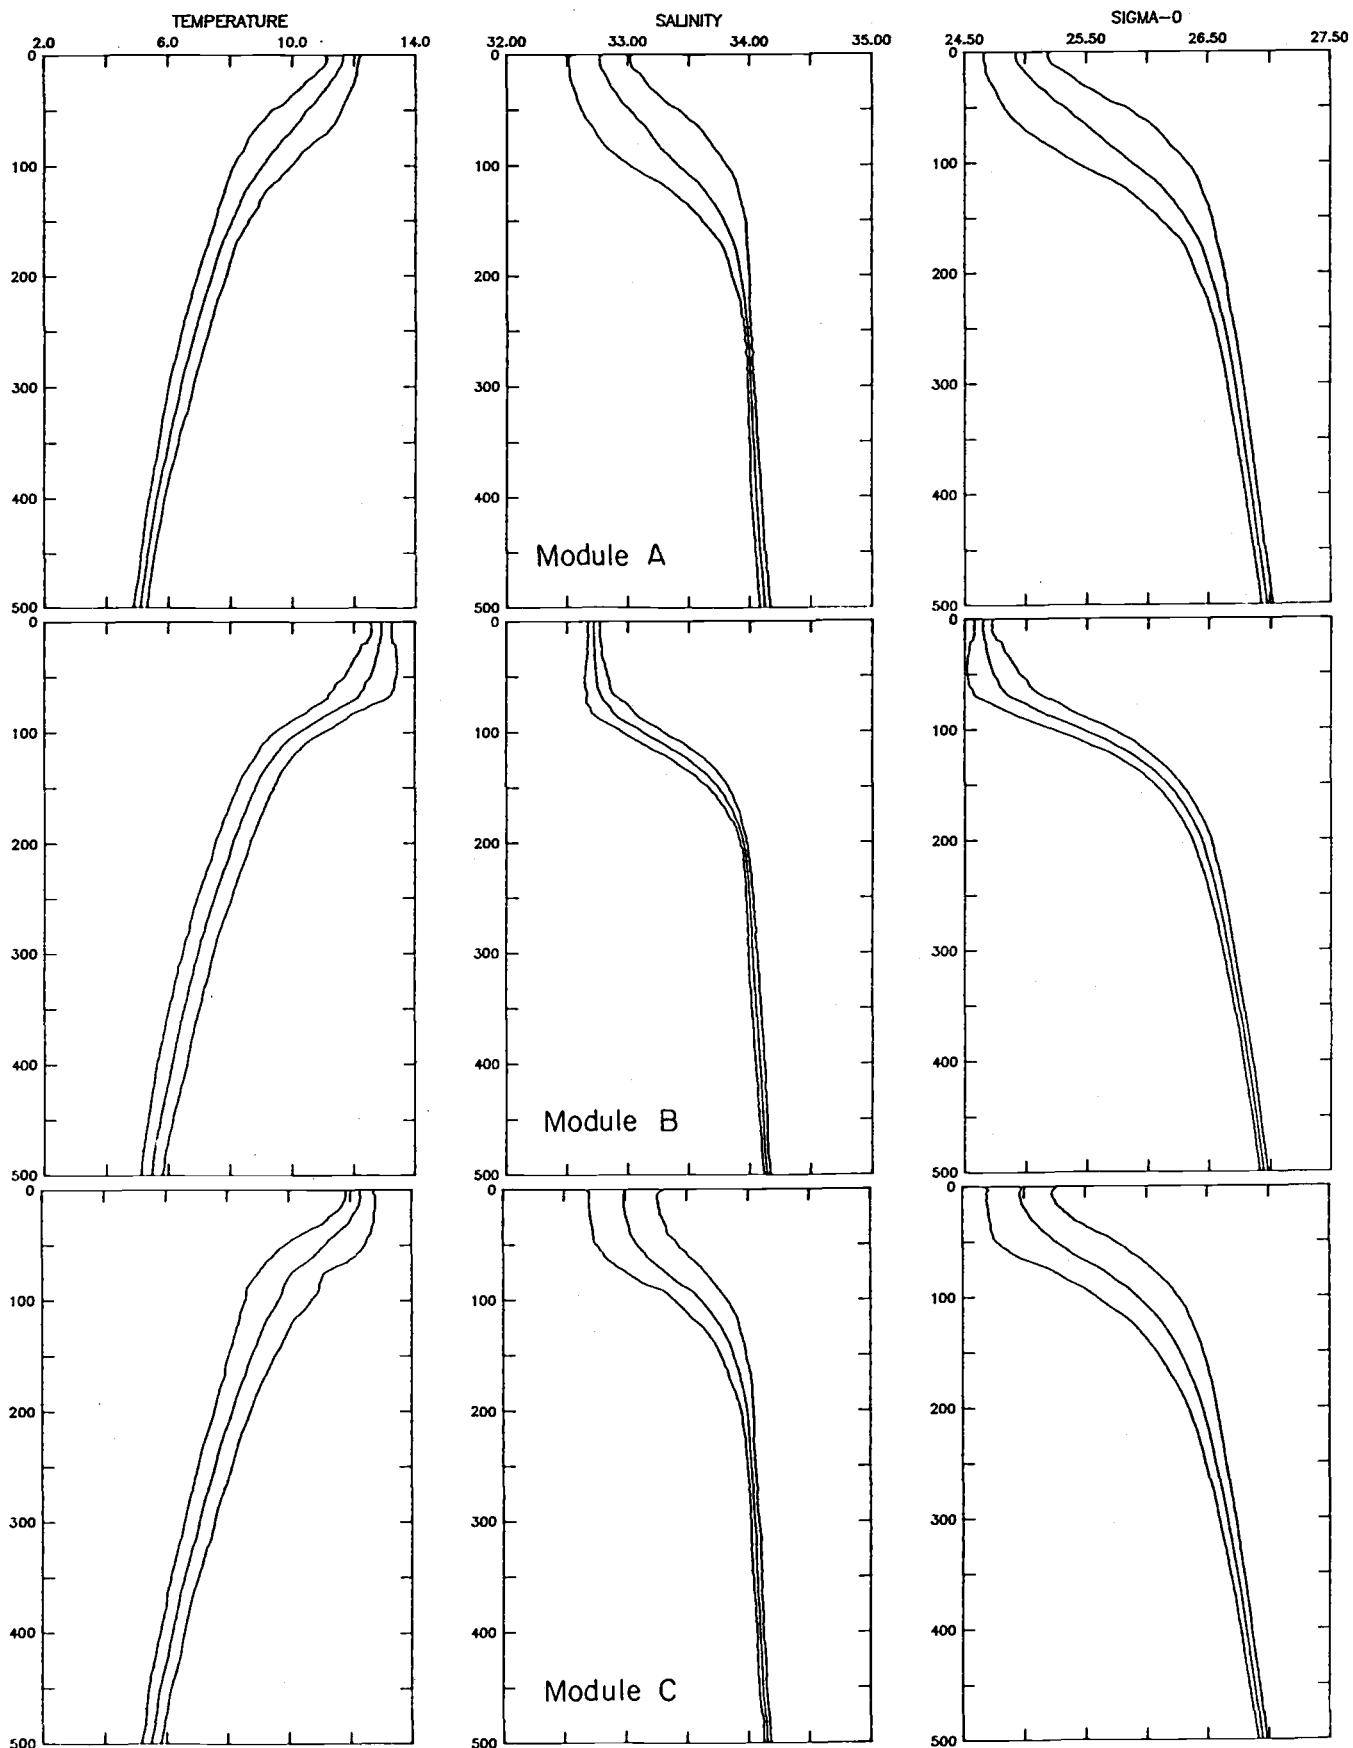

Figure 5. Overall averages, and the average plus and minus the standard deviation of temperature, salinity and potential density anomaly, calculated and displayed as a function of pressure for modules A, B and C.

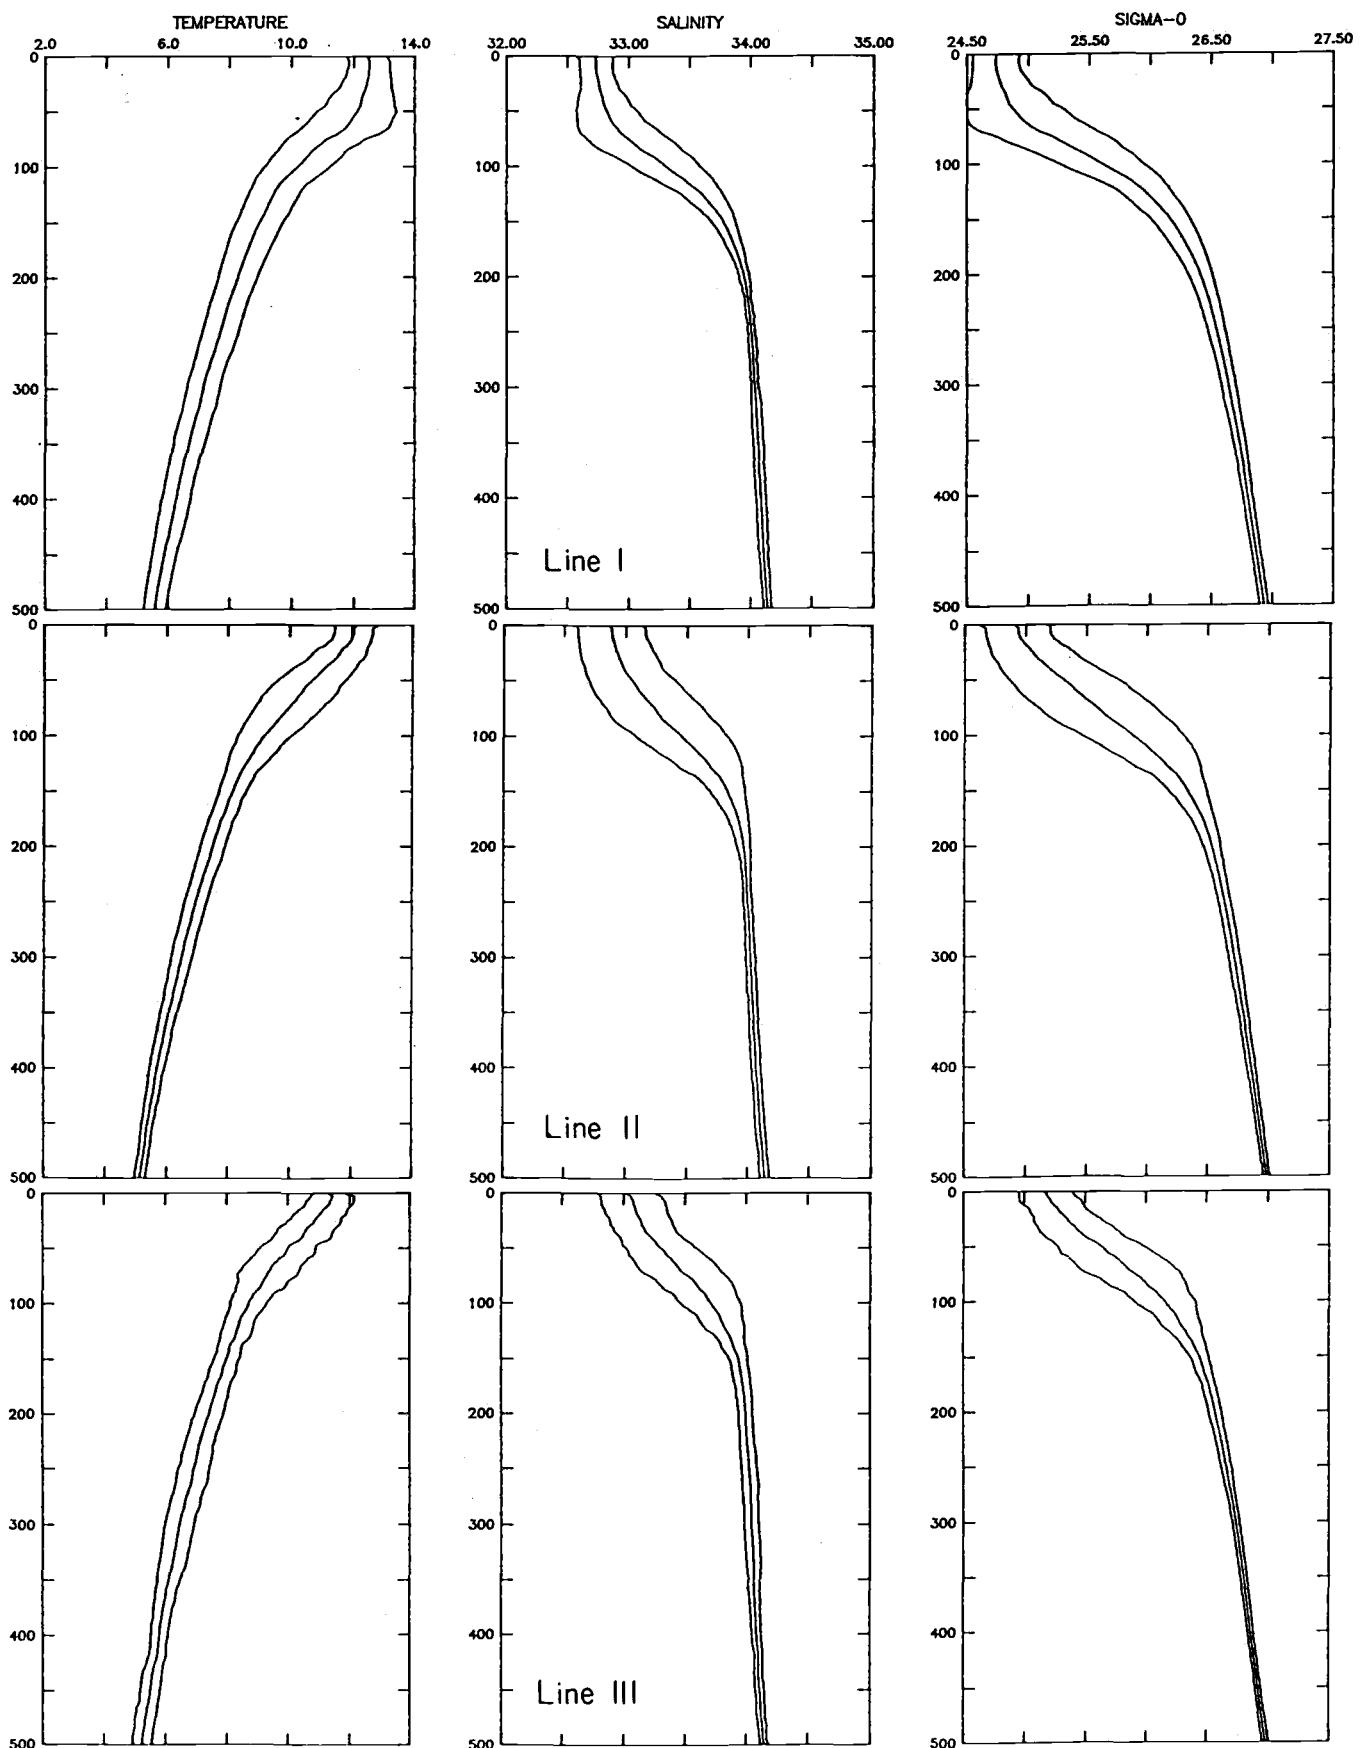

Figure 6. Overall averages, and the average plus and minus the standard deviation of temperature, salinity and potential density anomaly, calculated and displayed as a function of pressure for Lines I, II and III.

POTENTIAL TEMPERATURE

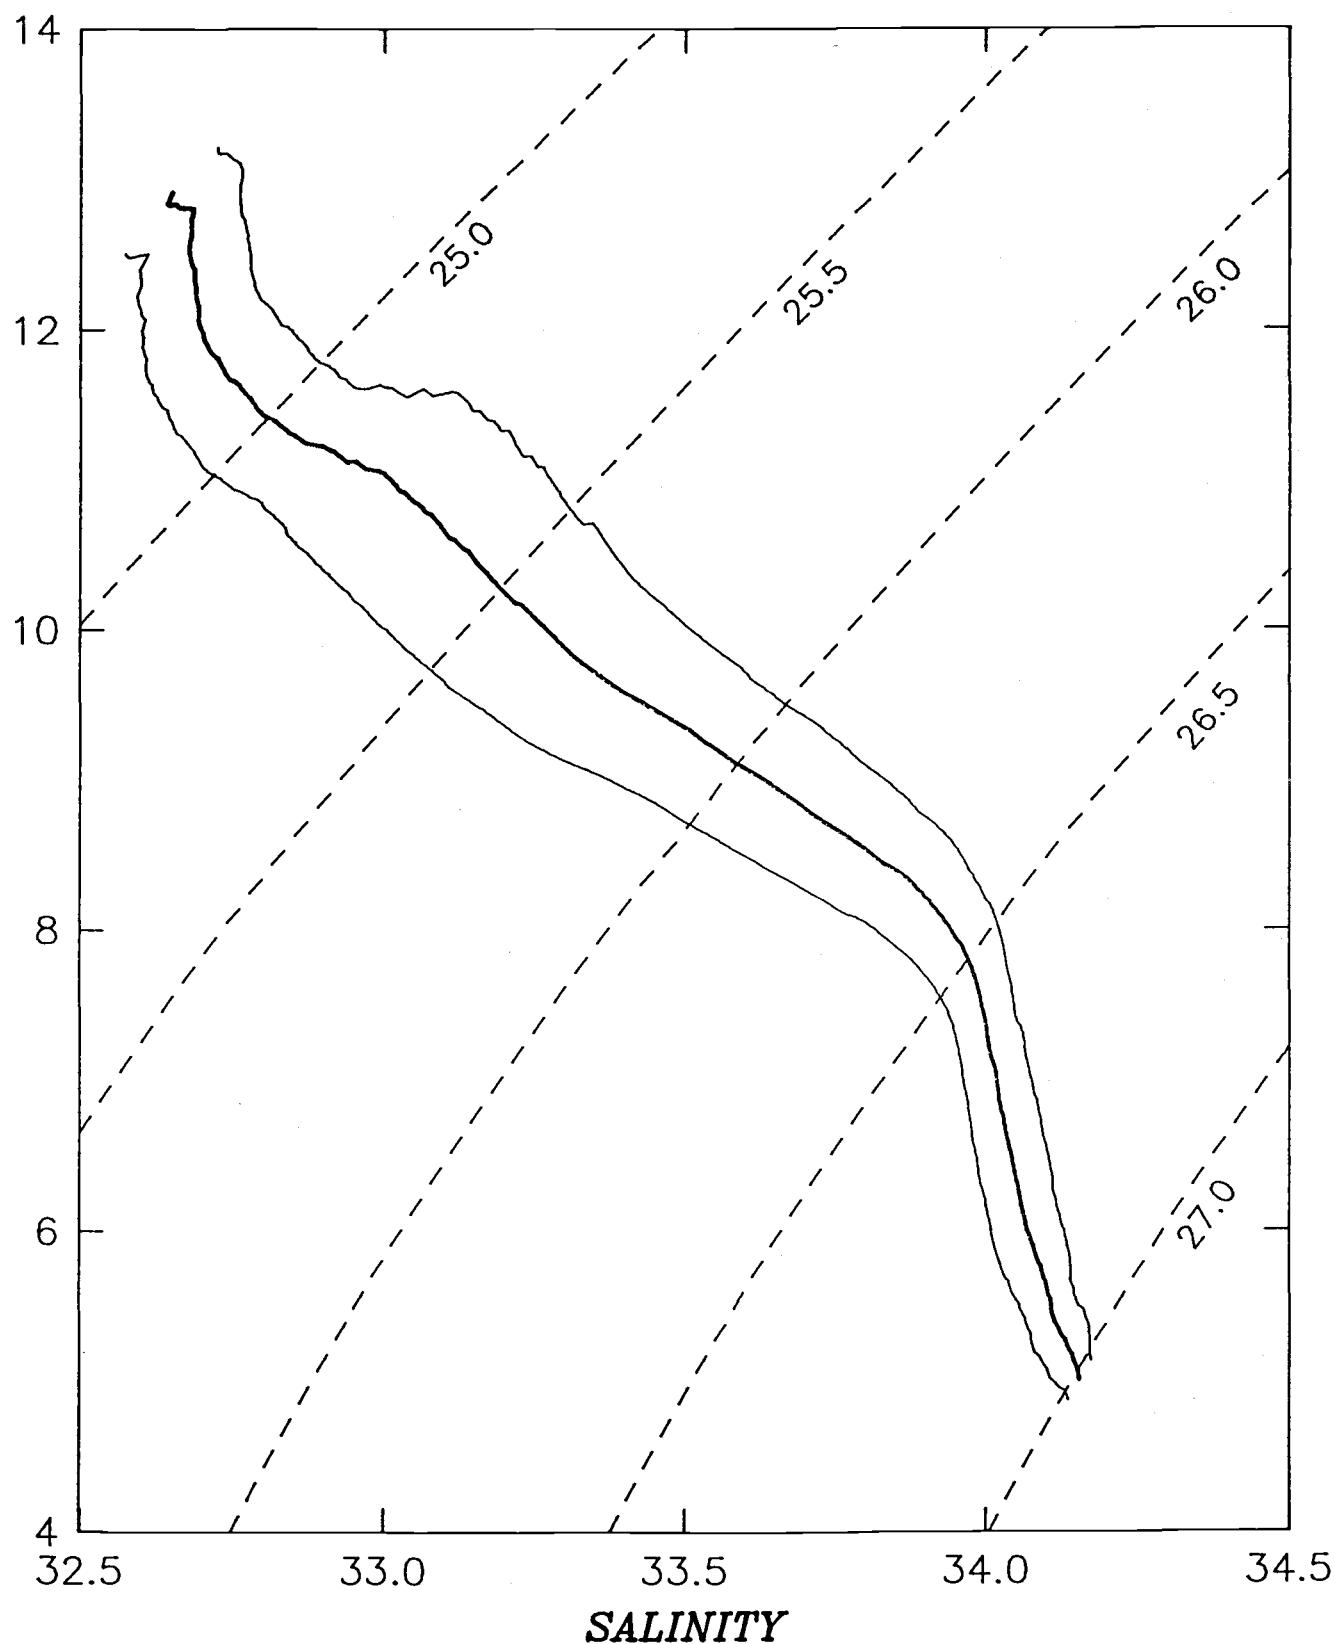

Figure 7. Average potential T-S curve calculated from the 98 CTD casts, and the average plus and minus the standard deviations of temperature and salinity, calculated as a function of sigma-theta (intervals of  $0.01 \text{ kg/m}^3$ ), and shown only for the density range covered by at least 10 stations. Dashed curves are lines of constant sigma-theta.

For each station, we also present tabulations of selected parameters at standard depths. Header information for each station includes:

STA NO	Consecutive station number
LAT	Latitude in degrees and minutes north of the equator
LONG	Longitude in degrees and minutes west of the Greenwich meridian
DATE	Day, Month, Year
TIME	Universal Time (Greenwich Mean Time)
PROBE	Serial number of the CTD probe
DEPTH	Sonic depth in meters, corrected according to Matthews Tables.

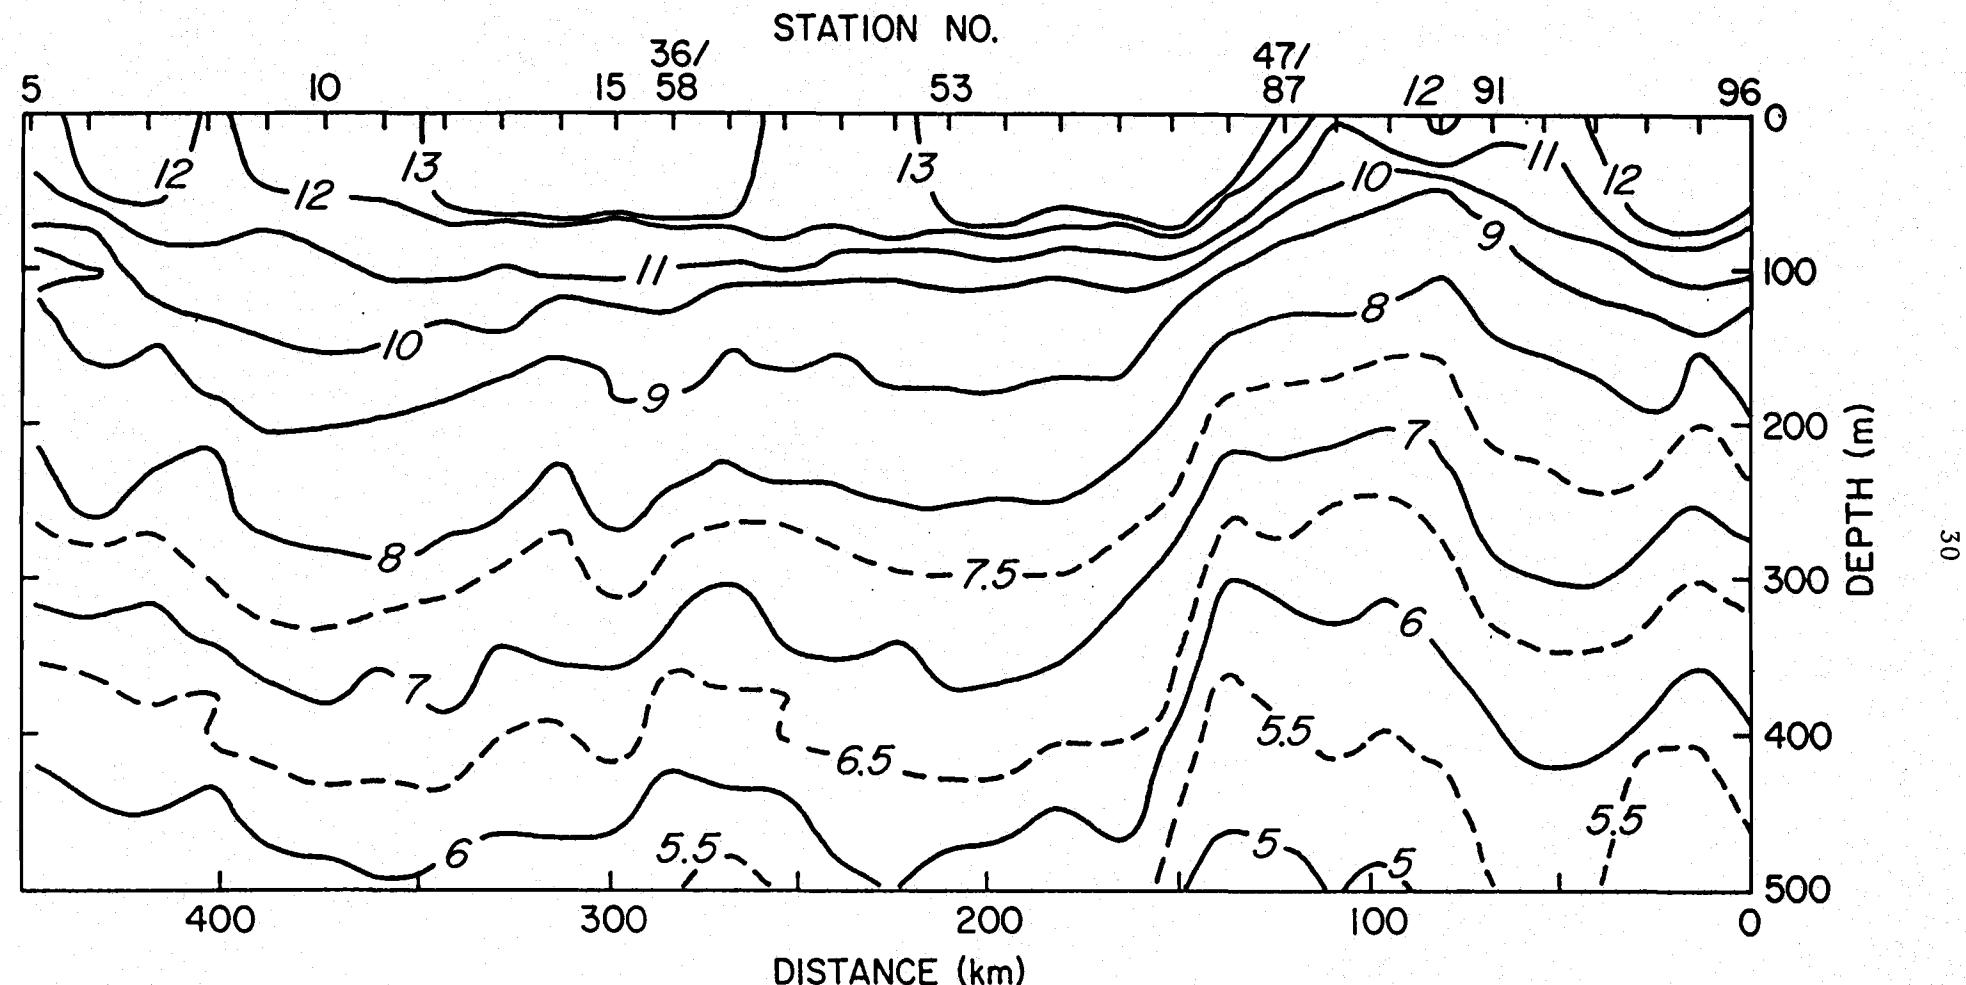

The data table for each station gives values of temperature in °C (TEMP), practical salinity (SAL), potential temperature (POTEN TEMP), potential density anomaly in kg/m<sup>3</sup> (SIGMA THETA), specific volume anomaly in 10<sup>-8</sup> m<sup>3</sup>/kg (SVA), geopotential anomaly (dynamic height, DELD) in dynamic meters, light transmission (TRN) in percent, and fluorescence (FL) in volts.
