Abstract

CTD observations were made along sections near Coos Bay at $43^{\circ}13'N$, off Crescent City at $41^{\circ}54'N$, off Eureka at $40^{\circ}51'N$, off of Half Moon Bay at $37^{\circ}25'N$, off of Pt. Purisima at $34^{\circ}45'N$, and along the Code Central and Pt. Arena lines near $39^{\circ}N$ during 8-15 September 1982; the maximum sampling depth was 1000 m. CTD observations were made in the vicinity of the LLWODP Pacific Study Area W-N west of Cape Mendocino between 17 and 23 September 1982, with a maximum sampling depth of 4377 db. This data report includes vertical sections, offshore profile plots, and vertical profile plots and listings at standard depth for each of the 76 CTD stations.

INTRODUCTION

Cruise W8209A was divided into two legs involving different projects. The purpose of Leg 1 was to replace current meter moorings and complete seven CTD sections between Coos Bay, Oregon and Pt. Purisima, California as part of the Large Scale West Coast Shelf Experiment (J. S. Allen, A. Huyer and R. L. Smith, principal investigators). Leg 2 of Cruise W8209A was one of a series of cruises of the Low Level Waste Ocean Disposal Program (G. R. Heath, principal investigator) to study the deep circulation and sea floor characteristics at Pacific Study Area W-N, west of Cape Mendocino, California. A complete discussion of the operations and a cruise narrative for Leg 2 was reported by Rea et. al. (1982). This report presents only the final CTD data from both legs.

The R/V Wecoma departed Newport on Leg 1 on 7 September 1982 and arrived off of Coos Bay at day break on the 8th. After replacing the Coos Bay Shallow mooring and recovering the Coos Bay Deep mooring, a second Coos Bay Deep mooring was recovered by dragging. A CTD cast was done near the Coos Bay Deep mooring (Station 1, Table 1, Figure 1) and the Five Mile CTD section was completed. On the 9th and 10th of September the Crescent City and Eureka CTD sections were completed (Figure 1) and the Eureka Shallow mooring was replaced. The Half Moon Bay mooring was replaced on 11 September and on 12 September the Pt. Purisima CTD line was finished and current meter moorings were recovered near the "Herman" and "Hondo" drill rigs in the Santa Barbara Channel. Two CTD casts took place next to the mooring sites (Stations 35 and 36, Table 1) and the ship departed for Monterey. A test of the portable hydro winch was done enroute.

The Wecoma made a quick port stop in Monterey on the 13th to off-load the portable winch and disembark J. Allen, J. Church, R. Smith and R. Still. The ship then proceeded to the Half Moon Bay CTD line and on

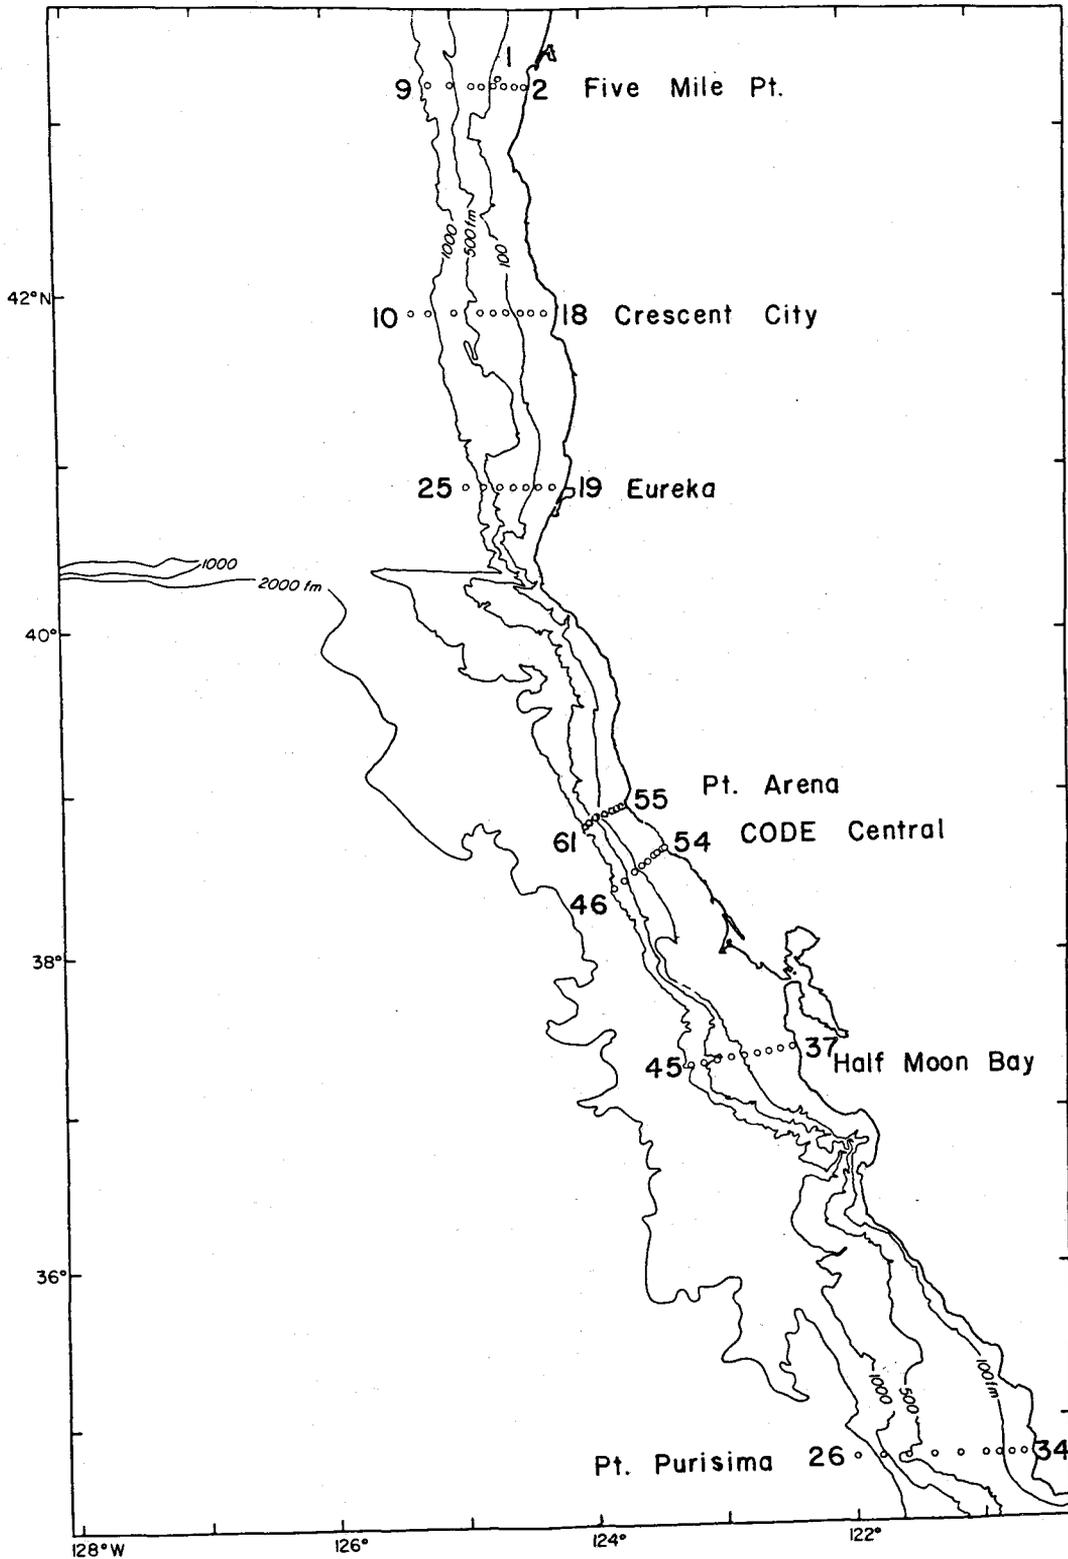

Figure 1. Location of CTD stations during W8209A, Leg 1, 8-15 September 1982.

September 13 and 14 that section and the Code Central and Pt. Arena sections were completed. The ship departed for Newport and a test of the CTD with the Rosette water sampler was done enroute (Station 62, Table 1). The ship arrived at Newport early on September 16. A total of 62 CTD casts were done on Leg 1 with a maximum sampling depth of 1000 m.

The R/V Wecoma departed on Leg 2 in the late afternoon of September 17, 1982 and returned to Newport on September 24. From the 19th to the 23rd five current meter arrays and 2 corrosion frames were recovered and one mooring was deployed (Figure 2). Seven deep CTD-Rosette casts (Sta. 63-69, Table 1, Figure 2) were completed in the vicinity of the moorings on September 19-21. Due to frequent stalling of the hydro winch during deep casts, the rosette was removed from the CTD and the last seven CTD casts (Sta. 70-76, Figure 2) on September 22-23 were done to a maximum depth of 1000 meters. The ship departed the Pacific Study Area on the afternoon of September 23rd.

Scientific Personnel on Leg 1 were John Allen, Robert Smith, Robert Still, Rich Schramm, Dennis Barstow, Henry Pittock, Mirth Miller, Jane Fleischbein and Henry Schaechterle from Oregon State University; Rich Heyner from Clatsop Community College; and John Church from C.S.I.R.O., Australia. Personnel participating in the CTD data collection on Leg 2 were Adriana Huyer, Mirth Miller, Rich Schramm, Dennis Barstow and Rich Heyner.

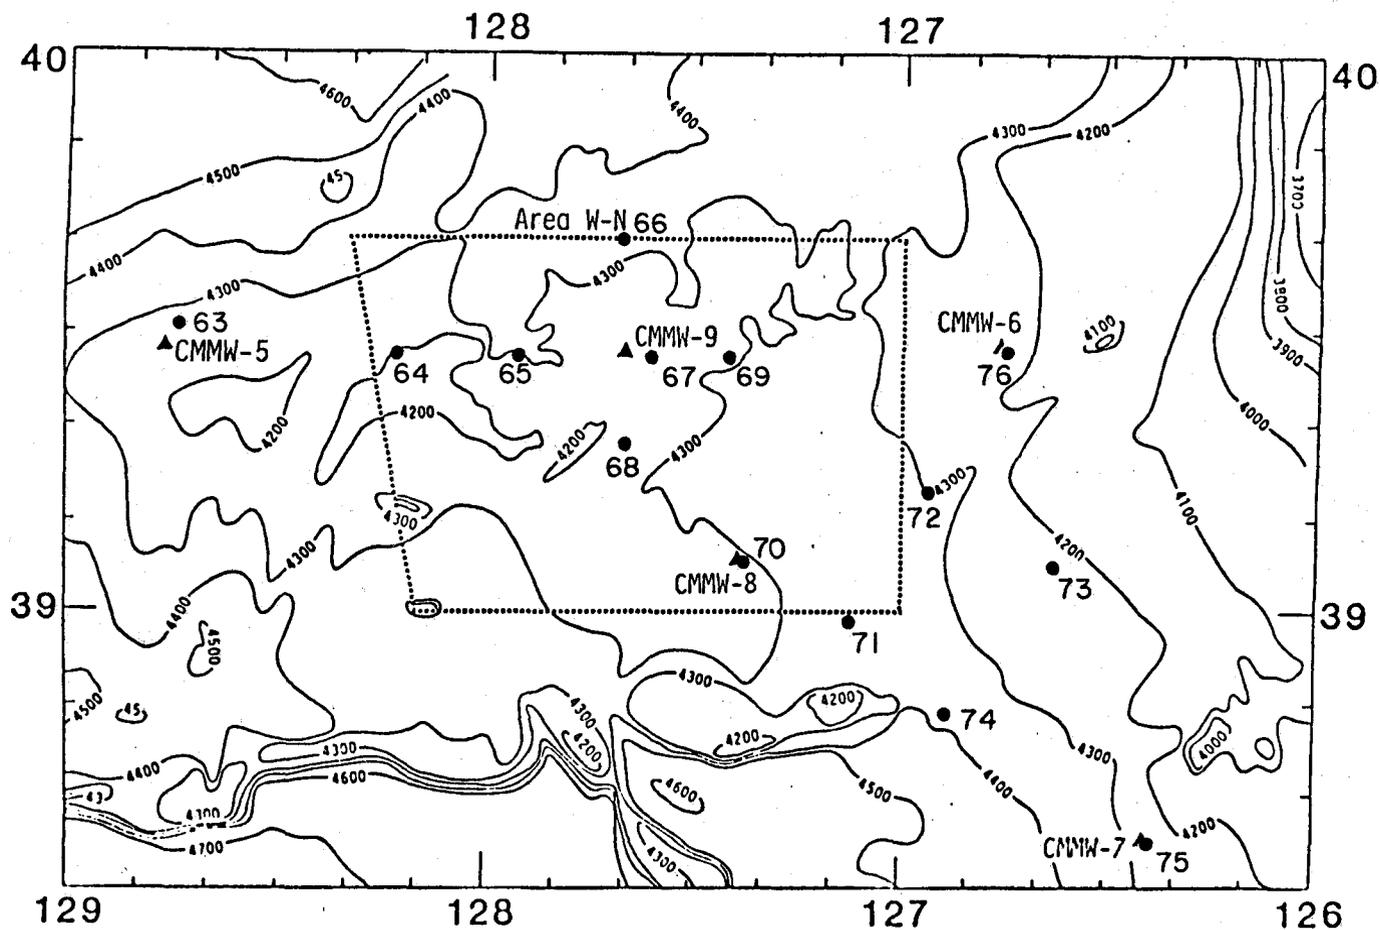

Figure 2. Location of current-meter moorings (triangles) and CTD stations (circles) occupied on cruise W8209A, Leg 2. The indicated bottom contours are uncertain in some regions; at a few CTD stations (e.g. Station 65) the observed bottom depth differed significantly from the depths inferred from this map.

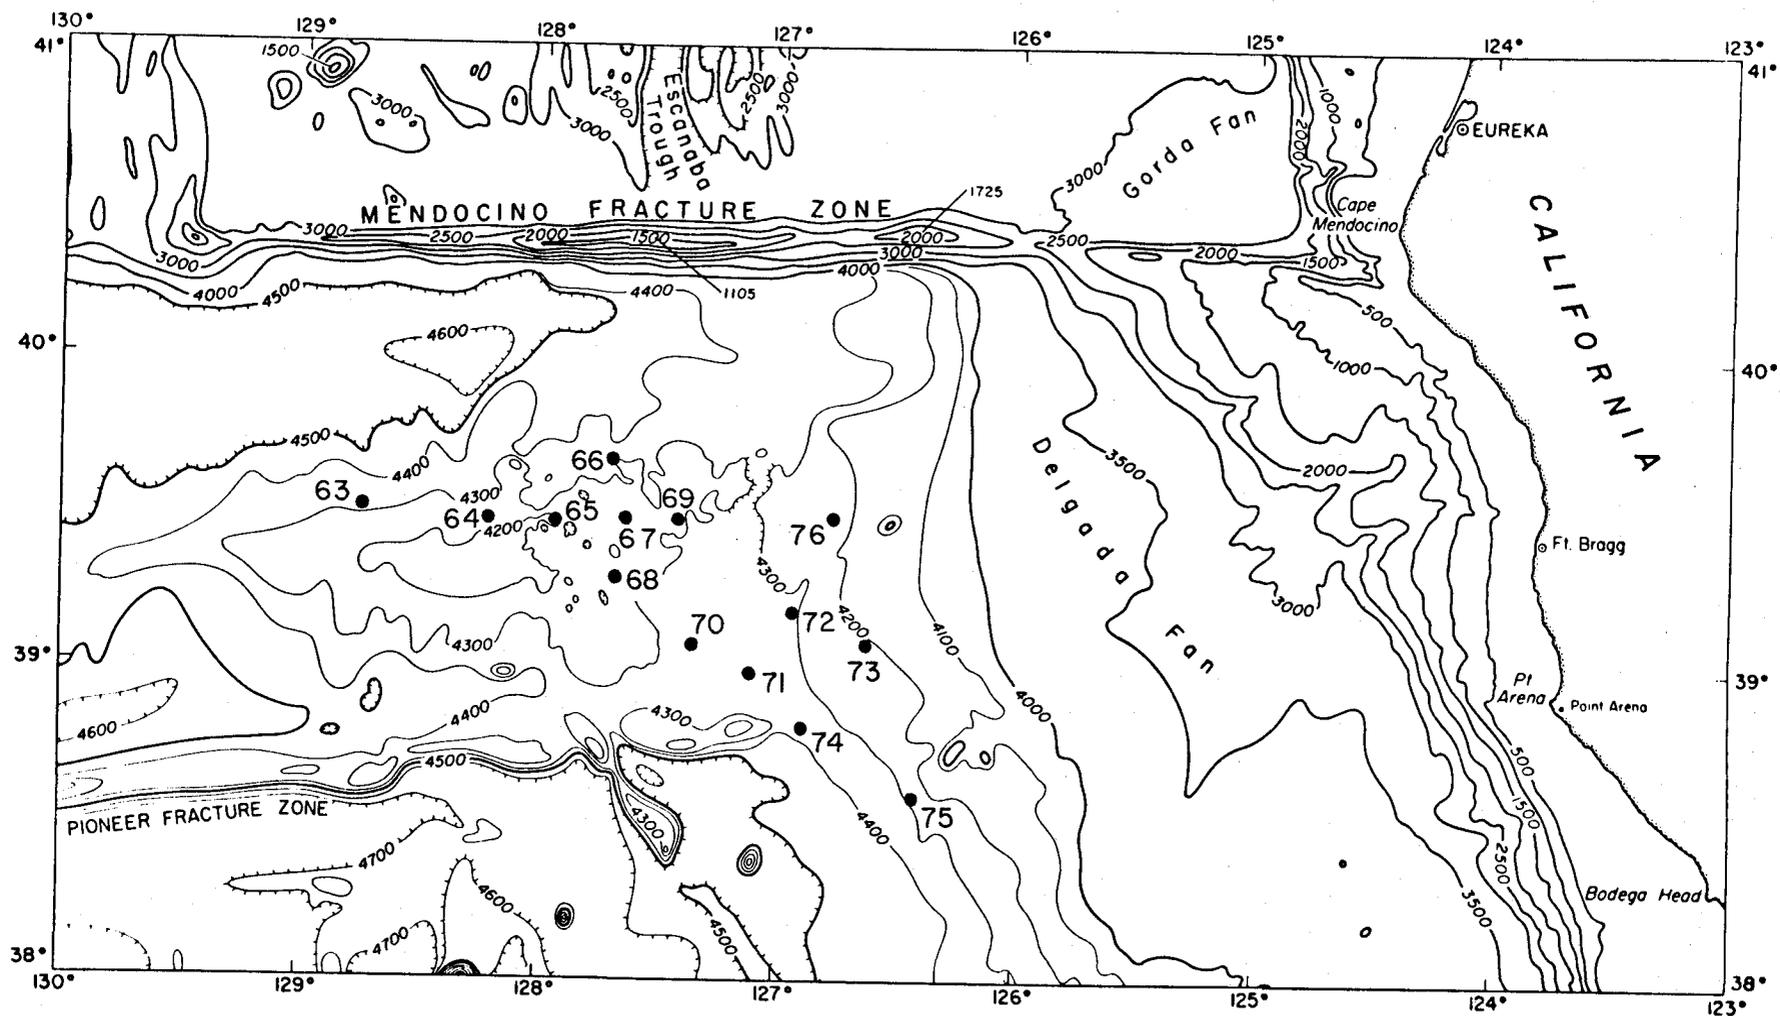

Figure 3. Location of CTD stations in Pacific Study Area W-N showing nearby bottom topography.

SAMPLING PROCEDURES, CALIBRATION AND DATA PROCESSING

A Neil Brown Instruments Mark IIIb conductivity-temperature-depth probe (CTD) was used to obtain continuous profiles of temperature and salinity versus pressure at each station. Characteristics of the CTD probe are presented in Table 2. Sampling procedures were identical with those described by Fleischbein et al. (1981). Probe #2561 with a 6500 db pressure sensor rating was used for all stations. During both legs, the CTD was equipped with Benthos Model 2110 Altimeter which measures the height above the bottom, with a typical range of 33 m and a resolution of 0.1 meter. The data from the altimeter was used primarily for studying the benthic boundary layer in the LLWODP Pacific Study Area. During the deep casts of the Leg 2 (i.e. Stations 63-69) the CTD was also equipped with a Sea Tech, Inc. 100-cm Transmissometer (S/N IM 80111) borrowed from the University of Rhode Island to see if there was a bottom nepheloid layer in the Pacific Study Area.

The CTD probe was calibrated for pressure, temperature and conductivity, by the manufacturer prior to delivery in the fall of 1980. *In situ* calibration data were also collected for temperature and conductivity sensors. At most stations a Niskin bottle equipped with 3 protected reversing thermometers was mounted about 2 m above the CTD sensors to provide calibration samples. During Stations 63-69 a rosette water sampler was mounted with the CTD, and duplicate salinity samples were drawn from one or more Niskin bottles on the rosette. The thermometers have an accuracy of $\pm 0.02^{\circ}\text{C}$ and are corrected using the results of calibrations done once every 2 years. Water sample salinity is determined by Guildline Model 8400 Autosol

salinometers with precision of better than $\pm 0.002\text{‰}$ and accuracy of $\pm 0.003\text{‰}$, using equations given by Bennett (1976).

CTD data are recorded at the actual sample depth after the bottle is tripped. Occasionally due to large wire angles the CTD and sample bottles do not remain at the same depth (and temperature) during soak time. When this resulted in relatively large differences between the sample and CTD temperature readings, these points were eliminated from the overall CTD-sample comparisons.

Duplicate salinity samples were drawn from the Niskin bottle at each station. Both sets were analyzed on OSU's Autosol #3. Because the set of salinity samples drawn first had two samples that had leaked, the second set of salinity samples was used for the final comparison.

Results of the comparison between *in situ* sample data and the CTD output are summarized in Table 3. The sample conductivity was calculated using the CTD temperature and sample salinity. CTD conductivity was corrected for the pressure and temperature effects on the cell prior to the comparison. The temperature differences are within the sampling and instrument errors so no further corrections were applied to temperature prior to processing the data. The conductivity differences had a mean offset of -0.002 and standard deviation of 0.002 which are within the sampling errors so no correction was applied to the CTD data.

The altimeter emits and measures the return time of a downward acoustic signal about once per second. In the CTD unit this time is converted to the height from the bottom in decimeters. If no return signal is detected, the height is arbitrarily set to -88 . This number is then merged into each CTD data scan sent to the deck unit (once every 32 ms). The number remains

Table 2. Characteristics of the CTD probe used.

Probe	Sample Interval	Temperature Time Constant	P	Sensors		
				T	C	
2561	32 ms	280 ms	Range: 6500 db Resolution: 0.1 db Accuracy: ± 6.5 db	-2 to 30°C .0005°C $\pm .005$ °C	1 to 65 mmhos .005 mmhos $\pm .001$ mmhos	

Table 3. Summary of the comparisons between the Neil Brown CTD probe and *in situ* calibration data.

	No. of Samples	Mean Difference	Standard Deviation
Temperature (°C)	67	0.006	0.015
Conductivity (mmhos cm ⁻²)	75	-0.002	0.002
Salinity (‰)	75	-0.002	0.003

Table 4. Summary of calibration data for Sea Tech Transmissometer # IM 80111

	<u>Path: 100 cm Air</u>		<u>Path Blocked</u>	
	<u>Volts</u>	<u>CTD Output</u>	<u>Volts</u>	<u>CTD Output</u>
Manufacturer (14 June 1981)	4.35	--	-0.005	--
In lab, pre-cruise (Sept. 1982)	4.251	3481	-0.005	0000
At Sea, before Station 63 (19 Sept. 1982)	4.257	3486	--	--

the same until the next pulse is sent and received by the altimeter. The transmissometer measures the light transmitted by a collimated beam through a 100 cm path length, providing an analog output of 0 to 5 VCD, corresponding to 0 to 100 % transmission. This output is digitized by the CTD using the full integer range of 0 to 4095, merged into the data stream, and updated about once per second. No calibration constants were used in processing the transmissometer data, because we were interested primarily in the thickness of the bottom nepheloid layer as opposed to its exact clarity, and also because air calibration tests before and during the cruise were in good agreement with the manufacturer's original calibration (Table 4).

The procedures for processing the pressure, conductivity and temperature data were described by Gilbert, Huyer and Schramm (1981). Basically, the conductivity data are filtered with a recursive filter $C = \alpha C_{n-1} + (1 - \alpha) C_n$ where C_n is the conductivity of the current scan, C_{n-1} is the conductivity of the previous scan and α is the filter constant whose value in this case is 0.900. The salinity is then calculated from the temperature, filtered conductivity and filtered pressure. All scans with increasing pressure are sorted into 2 db bins, and 2 db averages are calculated for each parameter: temperature, salinity, pressure, height above the bottom, and transmission. At some stations, there was a sudden downward shift in conductivity that was probably due to detritus in the conductivity cell; the data from these stations were edited (Table 5).

Table 5. Stations edited during data processing.

Station no.	Depth of Jump in Conductivity	Remedy
12	257-263 db	Linear interpolation of processed salinity at 257-263 db
20	245 db	Linear interpolation of processed salinity at 244-246 db
27	509-511 db	Linear interpolation of processed salinity at 509-511 db
30	15-23 db	Linear interpolation of processed salinity at 15-23 db
43	15-19 db	Linear interpolation of processed salinity at 15-19 db
71	550-575 db	Cast stopped at 580 db, CTD brought up to 500 db and restarted. 3 min. gap at 515-517 db where recast data was joined to original cast data.

Table 6. Comparison of corrected sonic bottom depth from the ship's PDR, the maximum CTD depth and the altimeter reading for deep stations in the Pacific Study Area.

	Sonic Depth (ship's PDR) Z_B (m)	Maximum CTD Depth Z_{max} (m)	Altimeter Reading H (m)	$Z_B - Z_{max}$ (m)
63	4287	4279	6.6	8
64	4213	4205	5.4	8
65	3881	3864	--	17
66	4308	4302	4.6	6
67	4228	4232	2.5	4
68	4229	4224	4.1	5
69	4260	4240	26.9	20

For the deep stations in the Pacific Study Area, we compared the difference between the sonic depth reading of the ships PDR corrected by Matthew's Tables for variations in the speed of sound and the maximum depth sampled by the CTD with the height above the bottom as measured by the altimeter (Table 6). In general, there was fairly good agreement, but in one case (Station 65) the altimeter had not yet recorded any return signal when the PDR indicated the CTD was only 19 m above the bottom. The PDR record in this case suggested the presence of several hillocks: it is possible that the bottom slopes here were very steep and that the depth below the altimeter was greater than 33 m, the typical range of the altimeter. In another case (Station 67) the PDR depth was slightly less than the maximum CTD depth but there was no other evidence that the CTD touched bottom: we trust that the altimeter reading of 2.5 m above the bottom was more nearly correct.

DATA PRESENTATION

The CTD data from Leg 1 are summarized in vertical sections of temperature, salinity, and sigma-theta, contoured by hand. Tick marks at the top of each section indicate stations positions at which a CTD cast was made, and an inverted "T" marks the maximum depth of each cast. For each hydrographic section of Leg 1, we also show offshore profiles of surface temperature, salinity, sigma-theta, and dynamic height at 0, 100 and 200 db relative to 500 db. Dynamic height at shallow stations was computed using the extrapolation method described by Reid and Mantyla (1976); the extrapolated portion of each profile is dashed.

Vertical profiles of temperature, salinity and sigma-theta vs. pressure and listings of data at standard pressures are shown for each station of both legs. Header information for each station is as follows:

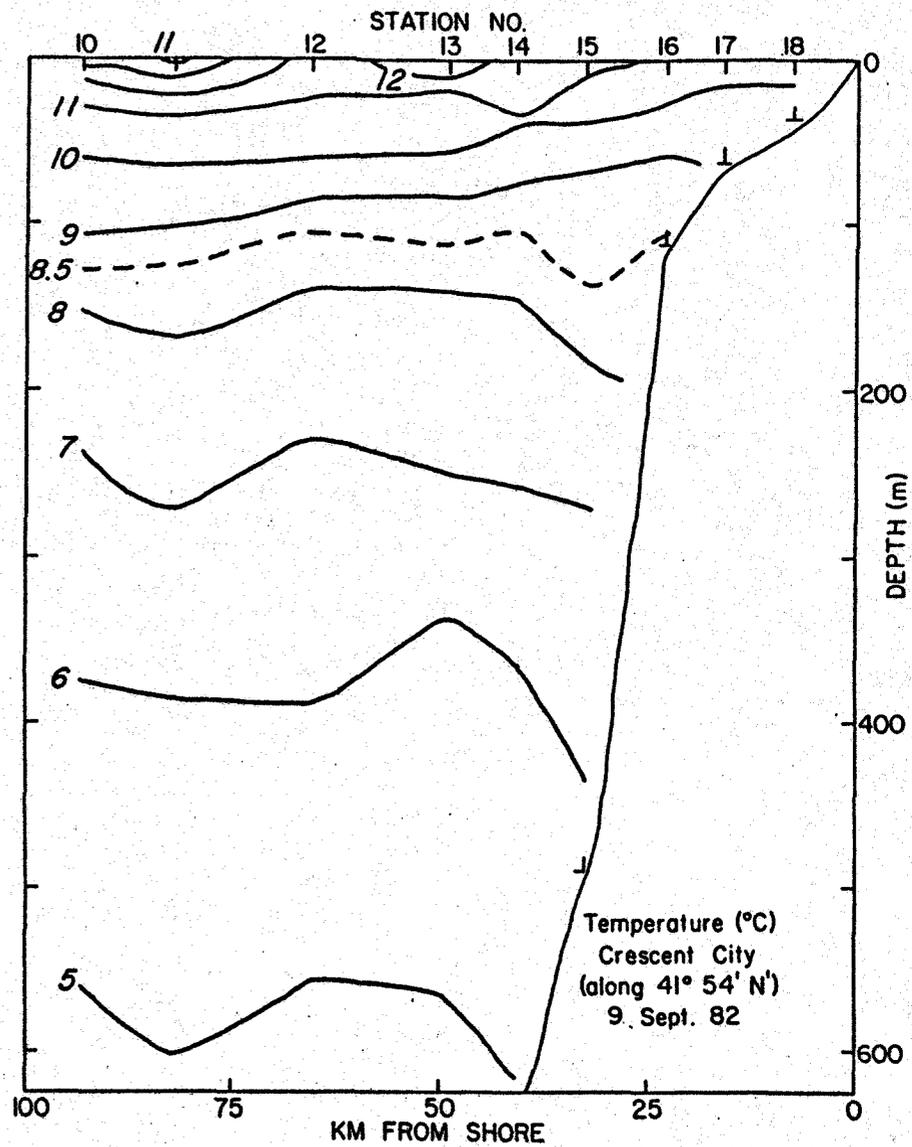

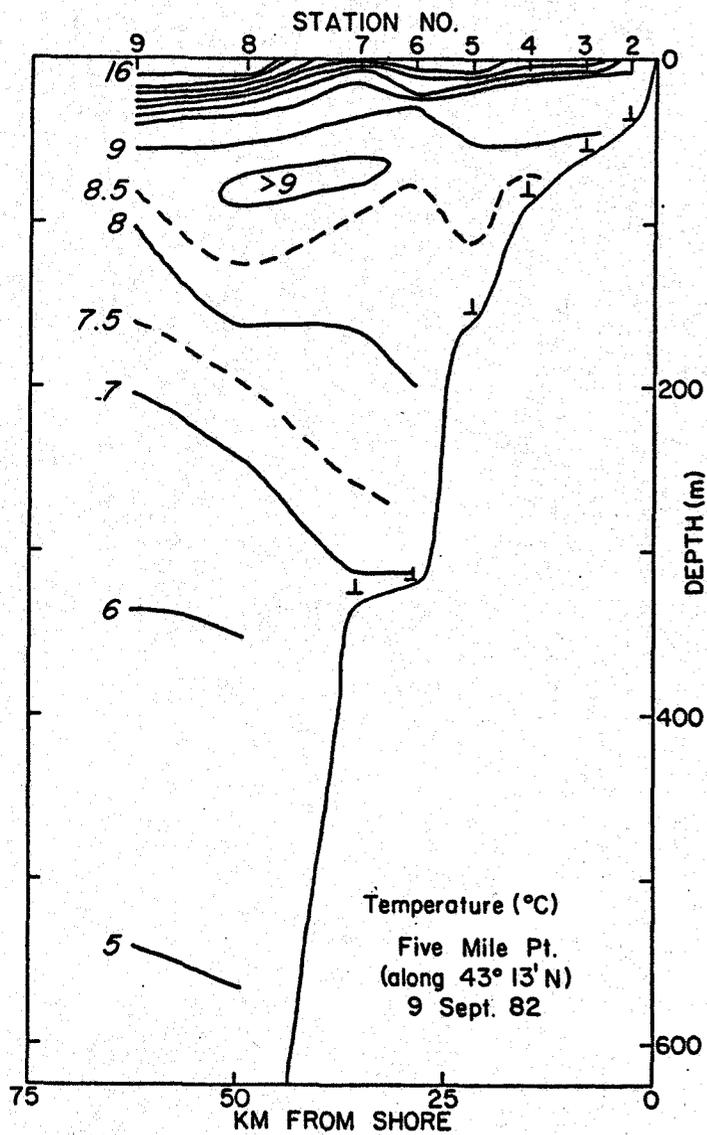

STA NO	Consecutive station number.
STATION	The CTD section name (initialed) and number of the station on the line (Refer to Figures 1 and 2).
LAT	Latitude in degrees and minutes north of the equator.
LONG	Longitude in degrees and minutes west of Greenwich.
DATE	Day/Month/Year.
TIME	Time in Greenwich Mean Time.
PROBE	CTD probe number.
DEPTH	Sonic depth in meters, corrected according to Matthews Tables appearing in the Handbook of Oceanographic Tables, U.S. Naval Oceanographic Office Publication SP-68 (1966).

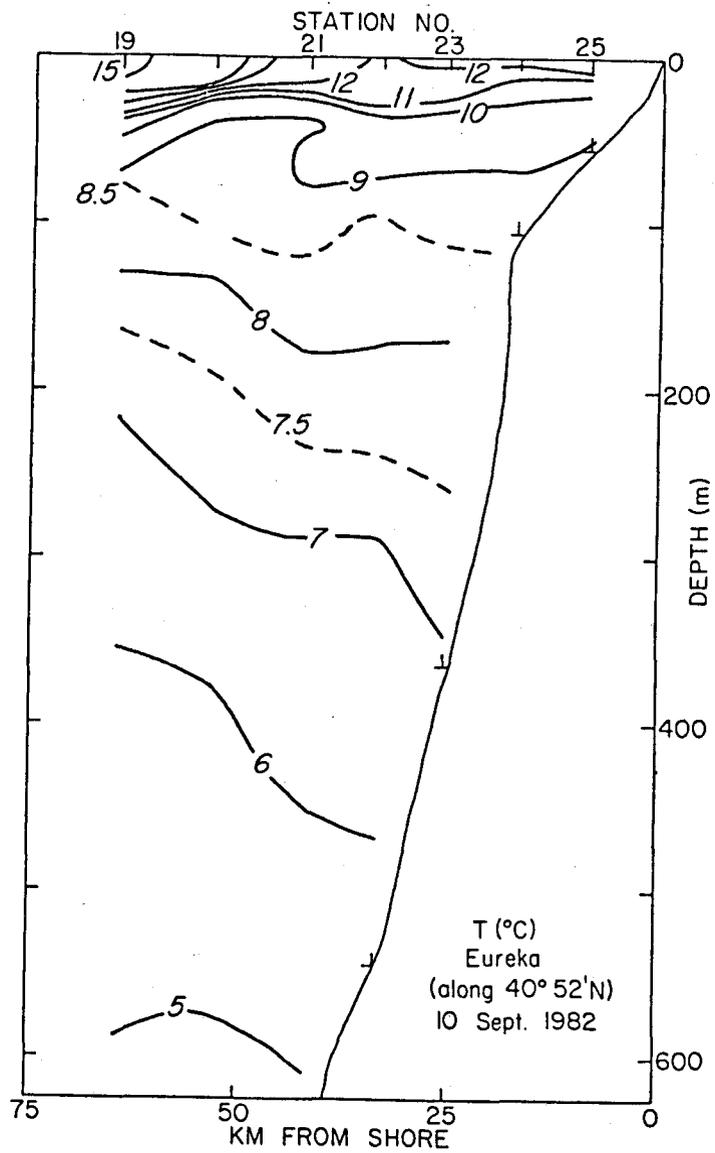

The data listing for each station gives values at standard pressures including observed and calculated parameters at the shallowest and deepest observations levels. Temperature (TEMP), salinity (SAL), potential

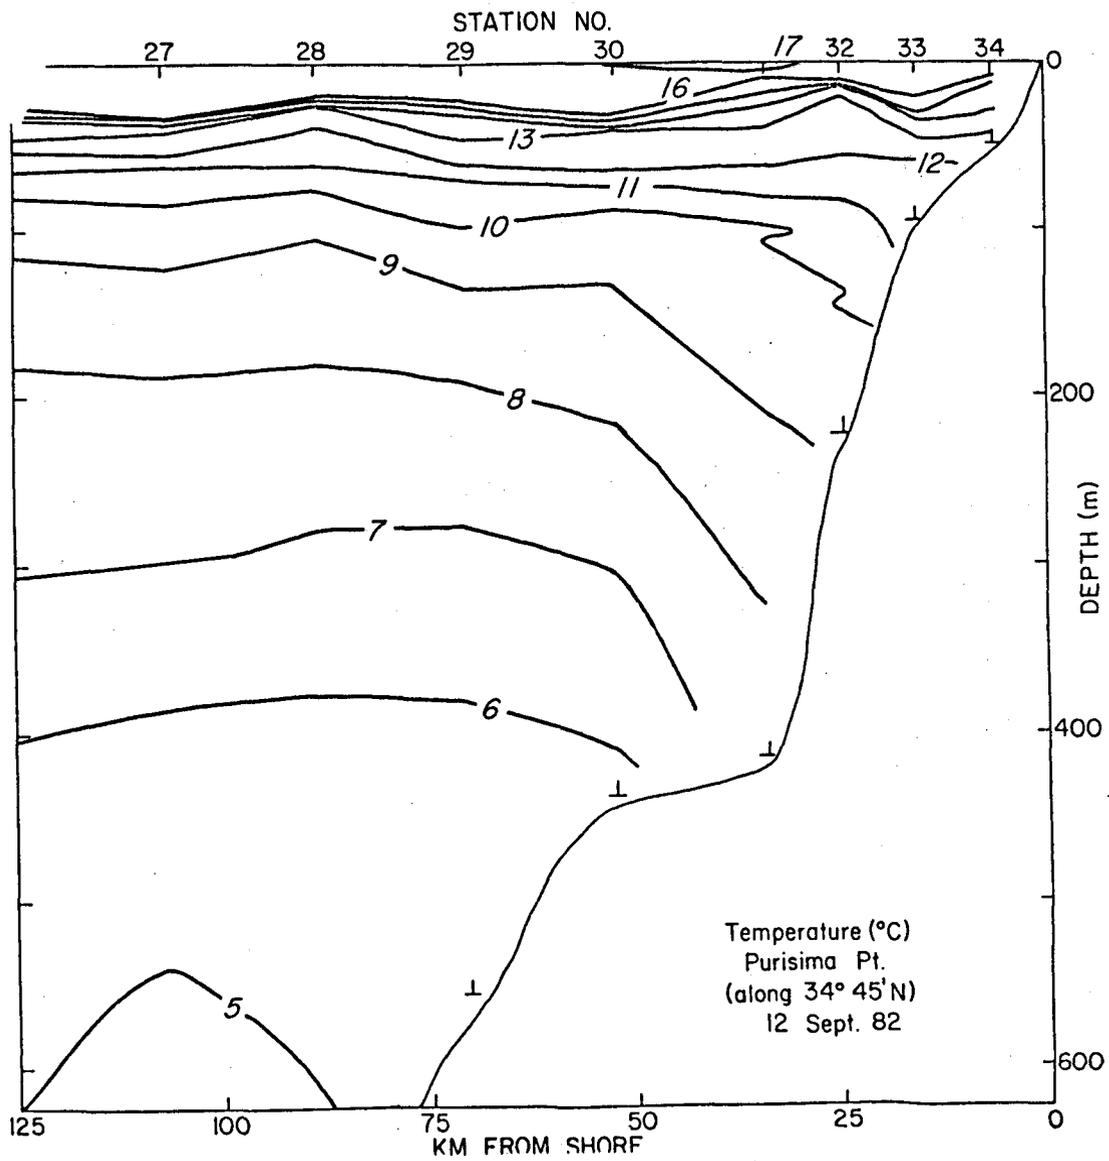

temperature, (POTEN TEMP), sigma-theta (SIGMA THETA), specific volume anomaly $\times 10^5$ (SVA) and dynamic height (DELD) in dynamic meters are given for each pressure (PRESS) in decibars. Computed parameters are calculated from the complete data array.

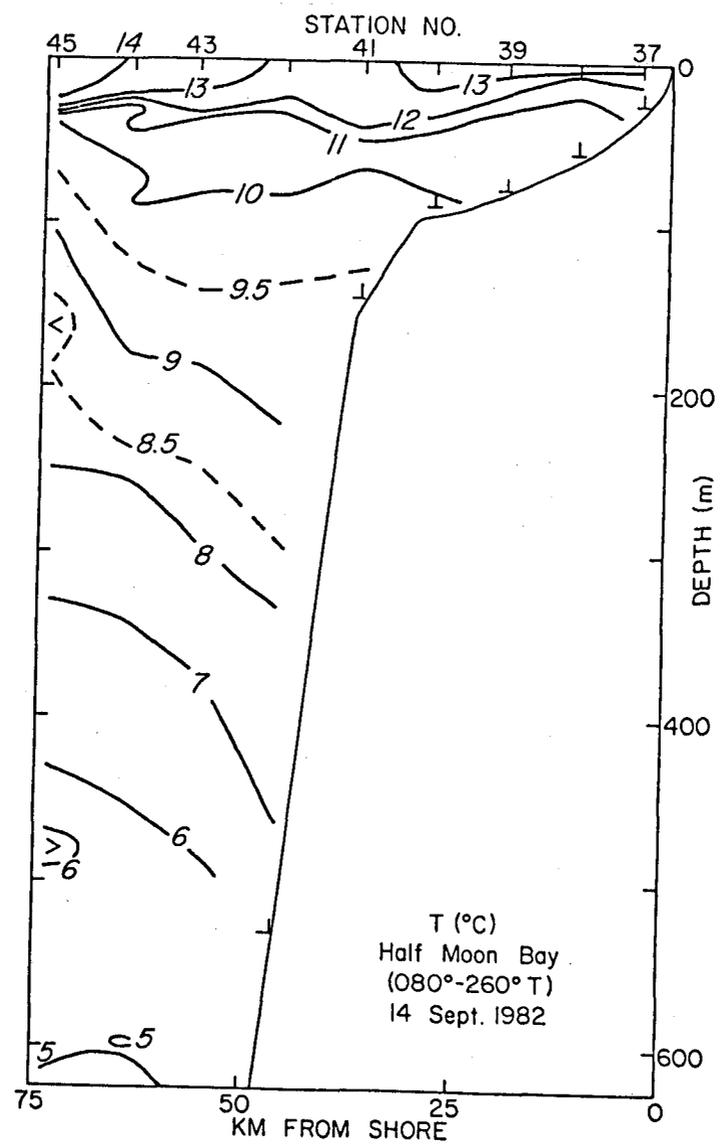

The near bottom profiles of potential temperature, salinity and sigma-theta vs. depth are also presented for each of the deep stations in the Pacific Study Area (i.e. Stations 63-69); in these plots, the bottom depth is indicated by a solid line. For these stations we also show vertical profiles of potential temperature and transmission vs. pressure.

Appendix. Abyssal salinities in the Pacific Study Area W-N

In earlier data reports (Fleischbein et al., 1981; Fleischbein and Huyer, 1982) we reported on deep CTD casts during two previous cruises to the LLWODP Pacific Study Area W-N. In light of the extremely low overall variability of salinity in the abyssal North Pacific (Mantyla and Reid, 1983), the salinity values of the deep calibration samples from all three cruises are re-examined here. Table A-1 lists all the salinity values from calibration samples collected at pressures greater than 3500 m within or near the Pacific Study Area during the three cruises. All samples were analyzed on Guildline Autosal Model 8400 salinometers. Except for W8102A, all samples were analyzed in the laboratory ashore after each cruise. The water samples were stored in 500 ml flint glass bottles which have screw tops with a polyethylene cone-shaped insert. The outside of each bottle top was wrapped with Parafilm to further reduce the possibility of leakage. Comparison of samples analyzed in March 1982 with duplicates analyzed in September 1981 soon after the W8108B cruise showed no significant salinity differences.

Only two deep samples were obtained during the W8102A cruise, and one of these had a salinity several parts per million lower than the other. Neither of these samples is within the Pacific Study Area. The samples from depths greater than 4000 during the other two cruises all have salinities between 34.687 and 34.694 ‰. The mode (and the median) of all samples below 3900 db is 34.689 ‰.

Table A-1. Deep and abyssal salinity sample values from three cruises to the LLWDP Pacific Study Area. Unless otherwise noted all samples were analyzed ashore after each cruise. Dates of salinometer runs and batch numbers of the standard water used are shown in the footnotes.

Cruise	Station	Bottom depth (m)	Lat (N)	Long (W)	CTD Pressure (db) at Sample Depth	CTD Temp. (C) at Sample Depth	Sample Salinity (‰) (Duplicates from the same Niskin Bottle)

 8 October 1982, P-92

These samples then indicate that the salinity of the abyssal water near 38.5°N, 128°W is 34.689 ‰. This is in good agreement with the maps presented by Mantyla and Reid (1983) which show that the abyssal salinity in this region is slightly less than 34.690 ‰.

In this data report, values of abyssal CTD salinities from depths greater than 4250 m (Stations 63-64, 66-69) are 34.692 or 34.693 ‰. These are slightly higher than the actual value as inferred from Table A-1 and the maps of Mantyla and Reid, but the difference is not larger than the stated accuracy (~ 0.003 ‰) of the CTD. Similarly, abyssal CTD salinity values reported for Stations 63-68 of W8102A (Fleischbein et al., 1981) are 34.687 and 34.688, only slightly below the probable actual value of 34.689 ‰. Also, most of the abyssal CTD salinity values reported for W8108B differ by only a few parts per million from 34.689 ‰: the range is 34.692 - 34.694 at W8108B Stations 18-26. However, the final stations (27-29) of W8108B all have abyssal CTD salinity values of 34.699 ‰, ten parts per million higher than the probable actual value. These data are likely in error by this amount.

ACKNOWLEDGMENTS

We thank W. E. Gilbert for his work in processing the data from both legs. The data collection and processing were supported by the National Science Foundation through Grant OCE-8026131 and by Sandia Laboratories Contracts SAN 73-7808 and SAN 52-3600.
