I

INTRODUCTION

One of the leading questions in the minds of foresters, loggers, and lumber manufacturers in the Douglas-fir region today concerns the future of the lumber industry as regards marketing its products. At the present time the principal market is in the Eastern United States. The principal competitor is the Southern pine region, and the principal problem is getting the product to that market at a low enough cost so that it may compete favorably.

In presenting this paper, the writer has drawn upon the information contained within the several references listed in the bibliography section of this report, and he has also drawn upon information presented in the classrooms of the School of Forestry, Oregon State College.

For the purpose of this report, the Douglas-fir region and the Pacific Northwest are used synonymously as are the Southern pine region and the South. The term "Eastern Markets" shall be used to include all lumber markets east of the Rocky Mountains.

II

PRESENT COMPETITIVE PICTURE OF DOUGLAS-FIR
ON EASTERN MARKETS

At the present time the Douglas-fir lumber industry is enjoying a period of relative prosperity. Lumber requirements which were not met in the recent war years have resulted in high demands now. As a result of the high demand for lumber for homes, wood-using industries, and industrial reconversion and expansion, there has been a very marked change in the lumber industry of the Douglas-fir region.

One of the most significant results of the very high demand is high prices. Never before in the history of the lumber industry have prices been so high. Private individuals and business concerns have been so anxious to get lumber for their own individual building enterprises that sheer competitive bidding, as it were, has forced lumber prices upward.

Results of high prices are reflected in the very large number of small operators who have gone into the logging and sawmill business. The lumber market has become a seller's market, and lower grades of lumber are readily sold. Second-growth stands which should have been left to form the basis of future crops are being logged. Wherever there is available timber and a possible logging chance, one finds a logging operation.

Another significant result of the high prices for lumber is that at the present prices a great deal of lumber can be shipped east by rail or by water and still make a profit despite the high freight rates. In normal times, however, only the better grades of construction

and finish lumber can stand the transportation charges and still compete favorably on the eastern lumber markets.

Douglas-fir is now competing successfully with southern pine, its greatest competitor, on the eastern markets. Lumber grades which in normal times could not be marketed profitably in these markets are now being marketed. The question that remains is how long will these lower grades be able to compete successfully, and what will be the picture when these markets are no longer available for these lower grades. Will the lumber industry be able to dispose of these lower grades when the demand for them drops off?

III

FACTORS WHICH LIMIT THE USE OF DOUGLAS-FIR ON EASTERN MARKETS

If Douglas-fir were able to meet its southern pine competitor on an equal basis, it would have certain advantages. While old-growth timber still remains, Douglas-fir has the advantage of being able to produce more clears and timbers of bigger sizes. In addition, the strength-weight ratio of Douglas-fir is higher. However, not all lumber is bought and sold on the basis of its desirable qualities unless for specialized use; price enters into the picture. Douglas-fir must necessarily be priced higher for several reasons. It is therefore at a disadvantage in competition with southern pine.

Transportation Charges

Transportation charges are the greatest single reason for the higher price of Douglas-fir on eastern markets. In normal times, as stated before, only the product that is desired for special purposes, such as construction timbers, is purchased in spite of the necessarily

higher price. Other less desirable grades must be marketed either locally, in California, or in other far western markets.

At the present time transportation rates are undergoing changes. In July, 1947, the railroads asked for an increase of rates from 15 and 25 per cent with a maximum of 12 cents per 100 pounds. Again in September, they increased the proposal to 38 and 28 per cent with a maximum of 18 cents per 100 pounds.¹

At the old rate, for example, for timbers weighing 2500 pounds per 1,000 board feet moving to New York City where the rate was 92 cents per 100 pounds, the freight charges would be \$23.00 per 1,000 board feet. At the rate proposed in July, that is, a 12 cent increase, the freight charges would be 104 cents per 100 pounds, or \$26.00 per 1,000 board feet. If we use the September proposal, we find that the freight charges would be \$28.00 per 1,000 board feet.

In October, 1947, the Interstate Commerce Commission granted a temporary increase of 10 per cent, and in January, 1948, the Commission granted an additional increase of 10 per cent, bringing the present rate to 110 cents per 100 pounds. This increase would bring the shipping cost of 1,000 board feet of timbers weighing 2500 pounds to \$27.44 if the destination were New York City.

Southern railroads were also affected by the rate change proposal, but they still average some forty cents per 100 pounds lower than the Douglas-fir region. From Hattiesburg, Mississippi, for example, to New York City, for timbers weighing 2,500 pounds per 1,000 board feet

¹

Information from a personal letter from K. C. Batchelder, Traffic Manager, West Coast Lumbermen's Association.

and a freight rate of 54 cents per 100 pounds, the freight charges would be \$13.50 per 1,000 board feet. Since this example is figured at the pre-July rate, the advantage enjoyed at that time by the southern pine over the Douglas-fir was \$9.50 per 1,000 board feet. Each increase since that time has been correspondingly the same for the southern railroads, and the southern pine advantage is still \$9.50 per 1,000 board feet.

According to a personal letter from the late W. G. Tilton of the West Coast Lumbermen's Association, lumber can be shipped to the eastern seaboard at a slightly lower cost by water. However, handling charges in unloading from the ship and reloading on freight cars for shipment inland, plus the railroad freight charge, limit the distance of the inland freight haul. Charges are on a cubic volume basis, but for convenience in estimating costs they have been set at \$25.00 per 1,000 board feet for shipment to New York City. Because lumber shipped by sea is more unprotected than that shipped by rail, only the common grades are shipped in this manner.

Southern Pine Competition

In addition to the freight rate advantage, the Southern pine region enjoys several other advantages over the Douglas-fir region. One of the most obvious advantages is its labor. A comparison of the average hourly wage for logging and sawmill workers for October, 1946, shows that the average wage for the Southern pine region was 70 cents per hour.¹ At the same time, the average wage for the Douglas-fir

1

"Wages in Sawmills in the South", Monthly Labor Review, U. S. Bureau of Labor Statistics, Vol. 64, p. 1031 (June, 1947).

region was \$1.35¹ per hour. This advantage by the South can be lost, however, because of the increased labor union activity in that region.

The Southern pine region also has an advantage in the terrain on which its trees grow. The region is accessible in nearly all of its parts, and there is very little of the "rough" terrain which is the rule rather than the exception in the Douglas-fir region. Almost the entire Southern pine region is admirably suited to tractor logging, and tractors are rapidly replacing animals for yarding purposes. In addition to the ease of logging which the terrain affords, there is also a much better opportunity for intensive management of the forest stands. Thinnings can be made with relative ease, and they are readily marketed. Markets for these thinnings are nearby, and transportation to them is a minor problem. Developments in the Douglas-fir region which would allow for marketing this type of product may reduce this advantage.

The South is a region of rapid growth which, however, is not a clear-cut advantage since the Douglas-fir region is able to support very rapid growth in most of the timber stands. Nevertheless, the southern pines clear their boles at an earlier age than do the Douglas-fir and associated species. This factor gives the southern pine the advantage of marketability at an earlier age and rotations of shorter durations. Douglas-fir, however, produces a larger and taller tree which is more useful as heavy construction timber than southern pine.

Advantages of the Douglas-fir Region

The Douglas-fir region has the advantage of highly efficient

1

"Postwar Development on The Pacific Coast," Monthly Labor Review, U. S. Bureau of Labor Statistics, Vol. 64, p. 621 (April, 1947).

logging and manufacturing methods which are of very considerable importance in reducing the advantage of the southern pine over Douglas-fir. Volumes per acre are high, and volumes logged per man-day are considerably higher in the Douglas-fir region because of the heavy mechanization of the logging methods. Mr. Ralph W. Marquis, Forest Economist for the U. S. Forest Service, states in a personal letter to the writer that this efficiency in logging and in manufacturing is one of the principal reasons why the Douglas-fir region has been able to compete successfully. He further states, however, that the Pacific Northwest could lose this advantage.

The other advantage of Douglas-fir over southern pine is the quality of the product. As has been stated before, Douglas-fir has been able to compete on eastern markets as construction and special use lumber despite the necessarily higher price. Quality, then, has been one of the primary factors which has kept Douglas-fir on the competitive market.

Mr. Marquis states that a complete series of tests for quality of second-growth Douglas-fir is being conducted at the Forest Products Laboratory, Madison, Wisconsin. However, results of these tests have not yet been published. Mr. Tilton, in his letter, stated that "The grades of construction and special-use lumber from second-growth timber are ordinarily as high or higher than from old-growth timber". No definite conclusions can be reached on this matter, however, until the results of the tests at the Forest Products Laboratory are made known.

IV

PRESENT FOREST RESOURCE SITUATION
IN THE DOUGLAS-FIR REGION

With the demand for lumber very high during the recent war years and with the demand also very high in the postwar period, the old-growth stands of timber in the Douglas-fir region are being depleted at an alarming rate.

The present stand in the Douglas-fir region, according to the latest figures available, is 117,222,000,000 cubic feet.¹ With an estimated annual growth of 1,024,000,000 cubic feet and an estimated annual drain of 2,150,000,000 cubic feet, it is apparent that the drain is greatly in excess of the growth. However, since about thirty-five per cent of the total area within the Douglas-fir region is in virgin stands, an increase in the growth rate can be expected as the old-growth stands are cut off. The increase will not be as large as one might expect, however, because much of the area previously logged and now in a reproducing and growing state is on the better sites. A good percentage of the old-growth stand that is left is on the poorer and more inaccessible sites. Therefore, the reproduction which will come after logging the present old-growth stands will not produce wood as fast as the second-growth stands on the better sites which were logged first.

Much more serious, perhaps, than the growth versus drain situation is the depletion of many fine second-growth stands during the recent

1

"Gaging The Timber Resources of The United States," Report Number 1 from A Reappraisal of The Forest Situation, U. S. Department of Agriculture, Forest Service, pp. 50-56 (1946).

years of high demand for logs. These are the stands which should have been left to form the basis for future cuts. When the present old-growth stands are cut out, there may be a serious shortage of logs as the result of the present practice of cutting in second-growth stands. Then, in order to maintain full log production, it may be necessary to log the species which are now considered as undesirable and to log the younger age classes of Douglas-fir which are now considered uneconomical to log. Development of better utilization practices, however, may change this picture considerably.

V

DEVELOPMENT OF BETTER UTILIZATION PRACTICES

The need for a more complete utilization of the timber stands in the Douglas-fir region has been felt for some time. The research work of the Oregon Forest Products Laboratory at Oregon State College and the many research experiments being carried out by private concerns is directed toward a more complete utilization of our timber resources.

Today, on a typical Douglas-fir logging show, 67 cubic feet per 1,000 board feet or about forty per cent of the total cubic volume of the stand is left on the ground as slashing.¹ Seventy cubic feet per 1,000 board feet or about forty-two per cent of those logs which reach the mill is wasted or burned as mill fuel.² If all of the waste material could be utilized, the drain on the timber resources of the region

¹

"Wood Waste in The United States," Report Number 4 from A Reappraisal of the Forest Situation, U. S. Department of Agriculture, Forest Service, p. 7 (1947).

² Ibid., p. 11.

would be materially reduced and the competitive advantage of Douglas-fir would be strengthened. Mr. Marquis states in his letter:

"A more complete utilization of woods and mill waste can, as adjuncts of lumber manufacture, improve the competitive position of Douglas-fir lumber through a reduction in manufacturing costs. Today, in a typical sawmill operation, the lumber produced from a tree must pay the cost of logging and transporting a much greater volume of wood."

Undoubtedly, if the material now wasted could be marketed profitable, the costs attributed to lumber and log production would be much lower.

In addition to the full utilization of the timber that is logged, there is a distinct need of utilizing the unfavored species which are not ordinarily logged. If these species were utilized more fully, the life of the old-growth stands might be further extended toward the time when the second-growth stands are ready to cut.

Another utilization factor which might change the picture considerably would be the development of lumber remanufacturing industries on the West Coast. At the present time, a good deal of lumber is shipped to the eastern part of the United States, remanufactured into doors, window casings, and other specialty products, and then shipped back to the West Coast consumer. The price the West Coast consumer pays includes not only the freight from West to East and return on the lumber used in the product but also he must pay the freight from West to East on the material wasted in the remanufacturing process. If these products were manufactured on the West Coast, the West Coast consumer would not have to pay the freight of the product to the East and return, and the Eastern consumer would not have to pay the freight on the material wasted in manufacture. In this case, the remanufacturer on the West Coast would have a decided advantage over the remanufacturer in the Eastern United States.

VI

POPULATION INCREASE IN THE WEST

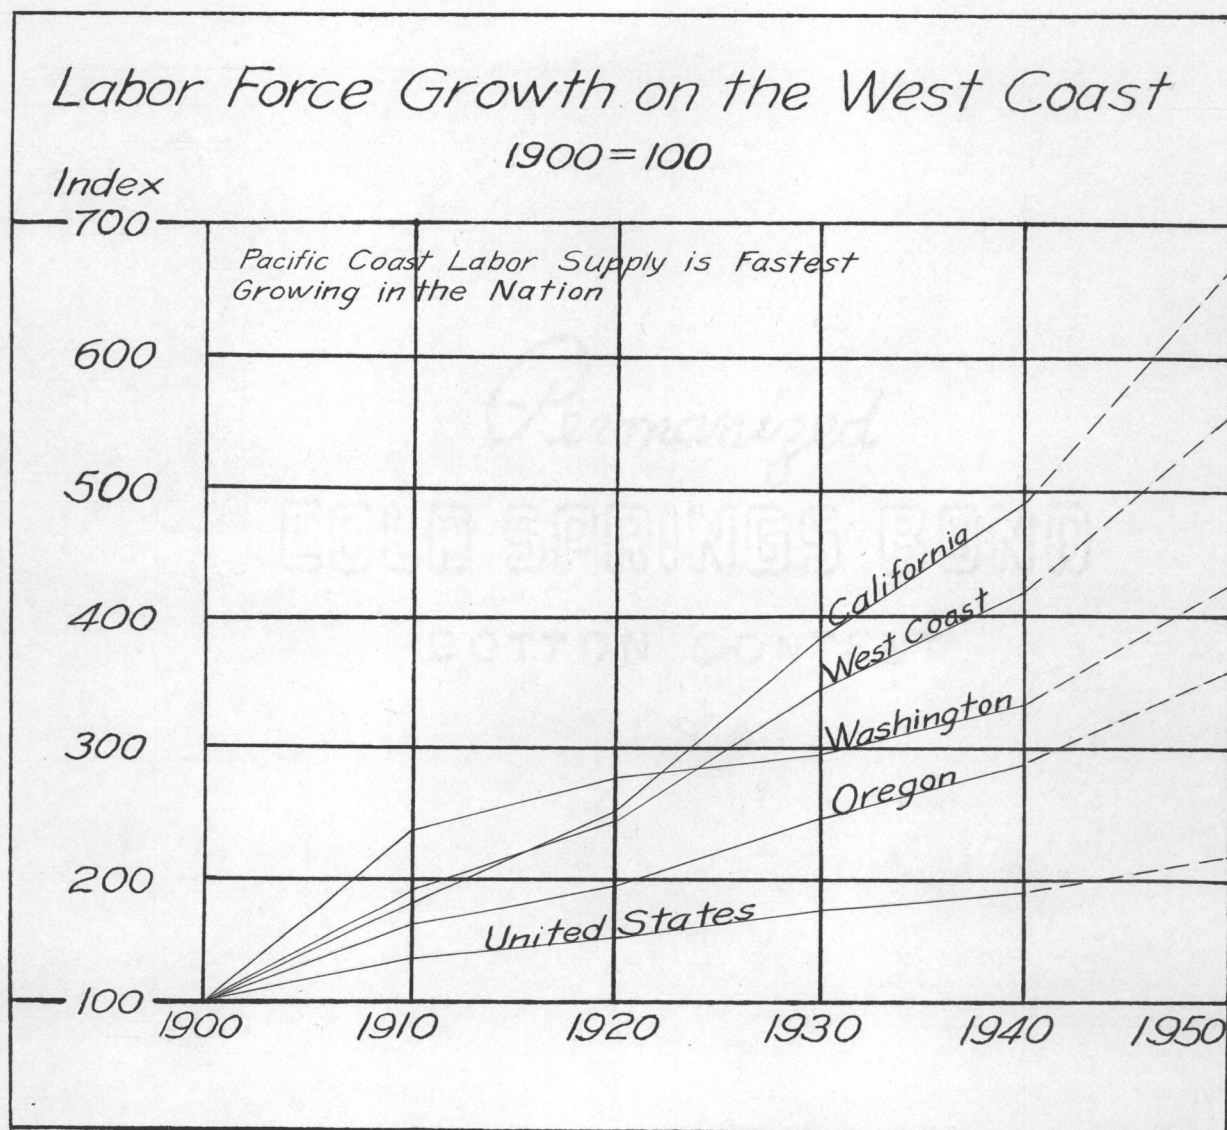

In comparison with the rest of the United States, most of the West Coast has been settled for only a relatively few years. About one hundred years ago, a few Spanish Dons and missionaries in California and a handful of trappers and traders in the Pacific Northwest represented the total encroachment of civilization upon the West Coast.

On January 23, 1848, James W. Marshall was operating a small sawmill for Captain John Sutter of Sacramento. The mill was located on the banks of the South Fork of the American River at what is now Coloma, California. While inspecting the tailrace of the sawmill on that historic morning, Marshall picked up a few grains of gold, and when the news leaked out, one of the greatest gold rushes in history began. This gold rush launched the West Coast upon a period of population increase which even now shows no signs of abatement.

During the recent war years, populations on the West Coast increased a great deal. Industrial development for the production of war materials was largely responsible for this increase. In back of this industrial development, however, was the wealth of natural resources, such as hydroelectric power, minerals, and timber, which are to be found in abundance in different localities on the Pacific Coast and in neighboring states.

While no complete information as to the total increase in the population on the West Coast during this decade will be available until the 1950 Census, estimates have been made by the U. S. Bureau of the Census and by the U. S. Bureau of Labor Statistics. These

Chart Showing Labor Force Increase
On The West Coast¹

¹

"Postwar Development on The Pacific Coast," p. 571.

estimates indicate a very marked increase in the West Coast population during and following the war years. In 1944, the Bureau of the Census sampled the population of the city of Los Angeles and recorded the following data:¹

| <u>Population of City of Los Angeles</u> | | |
|--|------------------|------------------|
| | <u>1940</u> | <u>1944</u> |
| Male - - - - - | 1,429,532 | 1,518,825 |
| Female - - - - - | <u>1,486,871</u> | <u>1,838,144</u> |
| Total - - - - - | 2,916,403 | 3,356,969 |

These figures indicate an increase of 440,566 persons or 15.3 per cent over 1940, and, since members of the armed forces were not included in the sampling, the figures do not give a true picture of the increase.

Another estimate by the Bureau of the Census for the State of California as a whole shows that between 1940 and 1946 the population increased by 32.6 per cent.²

The Bureau of Labor Statistics, U. S. Department of Labor, estimates that between 1940 and 1945, the labor force in the three Pacific Coast States increased by 1,591,000 to a total of 5,859,000 workers, an increase of 38.3 per cent.³

This great population increase should have a pronounced affect upon the future of the lumber industry in the Douglas-fir region. In 1944, 12,000,000,000 cubic feet of all timber, including 50,000,000,000

¹ "A Chapter in Population Sampling," U.S. Bureau of the Census, U. S. Government Printing Office, Washington, D.C. (1944).

² "State Shows Large Population Increase," The Sacramento Union, March 18, 1948, p. 5, col. 4.

³ Monthly Labor Review, Postwar Development on The Pacific Coast, p. 563.

board feet of saw timber, was cut from the forests of the United States.¹ Potential timber requirements for the United States during the period of 1950 to 1955, add up to 15,000,000,000 cubic feet annually.² It is estimated that by 1950 there will be 150,000,000 people in the United States.³ This means that the per capita utilization will amount to about one hundred and three cubic feet.

As the West Coast grows in population, so does its requirements for timber products. More and more of the output of Douglas-fir sawmills can be marketed on the West Coast, and these mills should be less and less dependent upon the Eastern lumber markets for their existence.

³ Ibid., p. 8

VII

CONCLUSIONS

The freight rates which Douglas-fir products must pay in order to enter into competition upon eastern markets are the industry's greatest single competitive disadvantage at the present time. An adjustment of these freight rates would be advantageous to the Douglas-fir lumber industry in the future.

The advantages which the Southern pine region now has over the Douglas-fir region may be reduced considerably as the result of future developments in the Pacific Northwest. These developments should allow for more intensive forest management through the marketing of material which is now uneconomical to market. The labor cost advantage which the South now has may be reduced considerably through union activity which is only now gaining a foothold in that region.

The advantage of the Douglas-fir region in its intensive mechanization may be lost to increased mechanization of logging and milling operations in the South. The quality of the product, however, is one advantage the Douglas-fir region may never lose.

The depletion rate of the Douglas-fir region is very high, and the drain is greatly in excess of the growth. However, with the development of higher utilization, the growth-drain situation may be somewhat more equalized in the future. Better utilization should also reduce the cost of logging and milling per unit cut and increase the competitive advantage of Douglas-fir.

Finally, the rapidly growing population of the West Coast

should furnish a market which could relieve the competitive pressure on the Douglas-fir lumber industry.
