BEARING STRENGTH OF WOOD AT ANGLE TO THE GRAIN¹

By

Forest Products Laboratory,² Forest Service
U. S. Department of Agriculture

The compressive strength of wood depends on the direction of the grain with respect to the direction of the applied force. It is highest parallel to the grain and lowest perpendicular to the grain, and for other angles has intermediate values. The ratio between the values perpendicular and parallel to the grain are not the same for different species of wood and also vary with the method of applying the load. For example, the basic stress of Douglas-fir is 1,450 pounds per square inch parallel to the grain and 235 pounds perpendicular to the grain, while for oak these respective values are 1,350 and 365. The safe load on a 1-inch bolt in a 6-inch Douglas-fir timber is 5,840 pounds parallel to the grain and 2,440 pounds perpendicular to the grain.

On account of this variation in the magnitude and relationship of the compressive strength parallel and perpendicular to the grain, the determination of the proper value for intervening angles has always been a difficult problem in timber design. To present values in tables for all the conditions would be impracticable. The bearing values for intervening angles, therefore, are usually obtained from the values parallel and perpendicular to the grain by the use of the Hankinson formula. This, however, involves a separate calculation for each individual condition and in order to provide a more convenient method the accompanying nomograph, based on the formula, has been developed by John A. Scholten of the U. S. Forest Products Laboratory.

The nomograph is based on the Hankinson formula, which is considered most applicable by the U. S. Forest Products Laboratory.

By means of this nomograph the stress or load for any intervening angle can be obtained from the stress or load parallel and perpendicular to the grain without any calculation. The symbols in the chart are represented

¹Original report by J. A. Newlin, Specialist in the Mechanics of Wood, published in Engineering News-Record May 11, 1939.

by allowable loads or stresses, but the formula is applicable for loads or stresses generally. The intercepts on any vertical line are proportional to $\sin^2\theta$ from 0 to 90 degrees. The scale of the chart was chosen primarily for convenient use with bolt loads, but for greater or lesser values or for different units, the magnitude of the scale can be adjusted to obtain greater accuracy without affecting the chart's applicability.

LEGEND
 P=ALLOWABLE LOAD OR STRESS PARALLEL TO GRAIN.
 Q=ALLOWABLE LOAD OR STRESS PERPENDICULAR TO GRAIN.
 N=ALLOWABLE LOAD OR STRESS AT INCLINATION θ WITH THE DIRECTION OF GRAIN.

EXAMPLE:
 GIVEN: P, AN ALLOWABLE BOLT LOAD PARALLEL TO GRAIN = 6,000 POUNDS; Q, AN ALLOWABLE LOAD PERPENDICULAR TO GRAIN = 2,000 POUNDS.
 REQUIRED: N, AN ALLOWABLE LOAD AT AN ANGLE OF 40° TO GRAIN.

SOLUTION: CONNECT WITH A STRAIGHT LINE 6,000 POUNDS ON OX (a) WITH THE INTERSECTION ON OY (b) OF A PERPENDICULAR LINE THROUGH 2,000 POUNDS, THE POINT WHERE THIS LINE (bb) INTERSECTS THE LINE REPRESENTING THE GIVEN ANGLE 40° IS DIRECTLY ABOVE THE ALLOWABLE BOLT LOAD, 3,285 POUNDS.

THE CHART IS A GRAPHICAL SOLUTION OF THE HANKINSON FORMULA:

$$N = \frac{P \cdot Q}{P \sin^2 \theta + Q \cos^2 \theta}$$
