Smoking fish at home—safely
K.S. Hilderbrand, Jr.

Three common ingredients in all fish-smoking recipes are salt, smoke, and heat. This publication points out that salt and heat are important for safety, and it explains the basic techniques for preparing delicious smoked fish with absolute safety. It also recommends refrigerated storage for all smoked fish.

Note that this publication applies to fish heated during the smoking process. "Coldsmoked" fish (which usually means fish kept below a range of 80 to 90°F) is a different product—and is not discussed here.

Smoked fish are good—but . . . !

Fish smoked without proper salting and cooking can cause food poisoning—it can even be lethal. Most food-poisoning bacteria can and will grow under the conditions normally found in the preparation and storage of smoked fish. Botulism is, of course, the most harmful of these bacteria.

There are two requirements for smoking of fish so that it will store safely with refrigeration (38°F):

1. You must heat fish to 160°F internal temperature and maintain this temperature at least 30 minutes. (See "Time-temperature requirements," page 4.)

2. You must salt or brine fish long enough to ensure adequate salt is present in the finished product. (See "3%/WPS" on page 4.)

Strict attention to both of these requirements is essential, for two reasons:

- It is difficult to predict in advance exactly how much salt a piece of fish will absorb.
- It is difficult to determine after smoking whether the internal temperature did indeed remain at 160°F for the full 30 minutes.

High-oil-content fish is usually the best for smoking. It absorbs smoke faster and has better texture. On the West Coast, some of these species are shad, sturgeon, smelt, herring, steelhead, salmon, mackerel, sablefish, and tuna. You can smoke any fish, however, without fear of food poisoning if you observe some basic principles. You will find these principles in the fundamental steps of all fish-smoking recipes: preparation, salting, smoking, and cooking, and storage.

Preparation

Different species of fish require different preparation techniques. Salmon are usually prepared by removing the backbone and splitting. Bottom fish are filleted. Small fish such as herring and smelt, should be headed and gutted before brining. (Columbia River smelt have traditionally been smoked whole because they have stopped feeding by the time they are harvested.)

In general, however, certain principles apply in all cases. First, use good quality fish. Smoking will not improve fish quality; it may, in fact, cover up certain conditions that could create food-safety problems later.

Thaw frozen fish in a cool place or in cool water.

Clean all fish thoroughly to remove blood, slime, and harmful bacteria. Keep fish as cool as possible at all times, but do not refreeze. When you cut fish for smoking, remember that uniformly-sized pieces will help achieve more uniform salt absorption without risk of over-salting. Do not let fish sit longer than 1 or 2 hours after cleaning and before smoking.

Kenneth S. Hilderbrand, Jr., Extension seafood technologist, Oregon State University, in consultation with Extension specialists at the University of Idaho and Washington State University.
Salting

Salt is what preserves smoked fish. Products with high-moisture content require more salt than “dry” products.

Without chemical analysis, it is hard to be certain that adequate salt has been absorbed by the fish. That is why proper cooking and refrigerated storage are essential for absolute safety. However, some rules of thumb are useful to approximate the proper salt level.

Salt the fish before smoking in a strong salt solution (brine); salting in a brine that is 1 part table salt to 7 parts water by volume for 1 hour will do in most cases. For instance, 1 cup salt with 7 cups water will salt 2 or 3 pounds of fish. (This proportion will read approximately 60°F salter on the salometer scale.)

About 30 minutes should do for a gutted herring. However, large or oily fish will require more time. Two hours for large chunks of a 30-pound salmon is a good starting place for experimenting.

Decrease the time for nonfat fish and for skinned fish. A final product that has a definite, but not unpleasant, salt flavor probably has absorbed enough salt.

Dry salting techniques are acceptable, and the same general rules apply.

However, brining should give more uniform salting than dry salting.

Many recipes call for lower salt brine concentrations than the 1 part table salt to 7 parts water formula given above—but for extended periods, 18 to 24 hours. These recipes may be sufficient, but it is safer to offer more opportunity for bacterial growth and possible spoilage later. In addition, these procedures tend to offer more opportunity for bacterial growth and possible spoilage later. In addition, these procedures may also increase the mess you must clean up later.

Rinse and air-dry all fish before smoking. This not only gives enough time for the fish to air dry evenly but also helps to prevent surface spoilage during smoking.

Smoke will not deposit well on a wet surface.

Proper drying conditions are available (cool, dry air), try placing the fish in the smokehouse with a thermometer at (80°F to 90°F), no smoke, and doors open. With a wood heat source, use a low, clean flame.

Smoking and Cooking

Cook the fish at 160°F internal temperature for at least 30 minutes at some time during the smoking “cycle.” This peak cooking temperature is probably the most important part of any fish-smoking recipe—and one part often forgotten when smoking fish.

Because you cannot determine the final salt content (without chemical analysis), proper cooking and adequate refrigeration are the only ways you can be sure a product will be botulism-free. A typical fish smoking cycle (see figure 1) should bring the fish to over 160°F internal temperature (minimum 6 to 8 hours; internal—not oven temperature).

However, smokehouses might provide 200°F to 225°F oven temperatures, you should have someplace in your kitchen oven to bake your final product in your kitchen oven. Waiting longer than 6 to 8 hours for that vital 30 minutes at over 160°F internal temperature presents a danger of spoilage caused by bacteria growing under ideal conditions (100°F to 130°F).

Remember: Smoke itself is not an effective preservative under most smokehouse conditions.

A standard meat thermometer will work for checking the internal temperature of the largest piece in the smokehouse. This should ensure that all the fish has reached 160°F. Some smokehouses may have cool spots. A long-stemmed dial thermometer inserted into the fish through a hole in the smokehouse wall may be desirable; it allows temperature monitoring without opening the door.

It is best to wait 3 to 5 hours before elevating the fish to the 160°F internal temperature. This is easier to do after most of the moisture is gone, and there will be less tendency for a baked fish flavor. In addition, there will be less bacterial growth and possible spoilage later. In addition, these procedures may also increase the mess you must clean up later.

Rinse and air-dry all fish before smoking. This not only gives enough time for the fish to air dry evenly but also helps to prevent surface spoilage during smoking.

Smoke will not deposit well on a wet surface.

Proper drying conditions are available (cool, dry air), try placing the fish in the smokehouse with a thermometer at (80°F to 90°F), no smoke, and doors open. With a wood heat source, use a low, clean flame.

Smoking and Cooking

Cook the fish at 160°F internal temperature for at least 30 minutes at some time during the smoking “cycle.” This peak cooking temperature is probably the most important part of any

Figure 1.—Typical internal fish temperature during smoking cycle.

Storage

Freeze or refrigerate your smoked fish (below 38°F) if you do not plan to consume it immediately. This is essential: The salt content is unknown, and there may be doubt about the time

“cured” in the fish due to improper refrigeration. All salmon products should be stored below 38°F if you do not plan to use them immediately."
Figure 2.—Basic components of a smokehouse. This drawing is not intended, nor should it be used, as a blueprint for building a smokehouse. It shows the features to look for in a smokehouse and their general arrangement. The key features are: (1) an independent source of heat for the pot of wood chips or logs; (2) a controllable vent, or flue, at the top; (3) a controllable draft at the bottom; (4) some thermostatic control over the oven temperature connected to (5) another heat source to raise temperature in the smokehouse to 200° to 225°F.
and temperature achieved in the smoking cycle.

You can retard mold growth on your smoked fish if you package it in a porous material such as cloth or paper toweling. This prevents "sweating," a process where moisture moves from the fish to the inside of the bag, causing a wet spot where mold can grow. This is especially severe if you place warm, plastic-wrapped fish in a refrigerator.

For extended storage (longer than 1 to 2 weeks), tightly wrap and freeze smoked fish. Little quality is lost in freezing smoked fish because of its low moisture content. (For instructions on correct packaging for freezing, see Home Freezing of Seafood.)

3½ % WPS

This phrase ("WPS" stands for "water phase salt") means that the salt content is 3½% of the moisture left after smoking. It is the minimum level of salt recommended by the U.S. Food and Drug Administration for commercial products. Although most home smokers do not have the ability to measure %WPS, it is well to keep in mind that a definite level of salt is required for safety—and that adequate refrigeration is the only safeguard for those who cannot measure WPS.

For further information

Most bookstores and sporting goods stores carry a variety of books on "smoke cooking." Most have delicious recipes and clear instructions. These, plus the use of common sense in following the principles outlined in this publication, will ensure safe, pleasing home-smoked fish.

Time-temperature requirements

While regulations for commercial fish smokers may permit a minimum temperature lower than 160°F (30 minutes), home smokers don't have the continuous time-temperature recording equipment necessary to ensure proper cooking.

Therefore, I continue to recommend 160°F (30 minutes) as the minimum internal temperature for home smokers.

Liquid smoke and sodium nitrite recipes

Liquid smoke and sodium nitrite are used in some home recipes. It is recommended that you do not rely on them for product safety. What you can rely on—and it's all you can rely on—is adequate refrigeration.

OSU Extension publications. Here are some suggestions for further reading. These publications are available from Publications Orders, Agricultural Communications, Oregon State University, Administrative Services A422, Corvallis, OR 97331-2119.

Shipping and handling: For orders up to $2.50, please include 25¢. For orders between $2.50 and $100, include 15%. For orders of $100 or more, or for 100 copies or more, call Agricultural Communications (503-737-2513) for a quote or reduced shipping rates.
